

SSFX (Space Sound Effects) Short Film Festival: Using the film festival model to inspire creative art-science and reach new audiences

Martin O. Archer¹

¹School of Physics and Astronomy, Queen Mary University of London, London, UK

Correspondence: Martin O. Archer
(m.archer@qmul.ac.uk)

Abstract. The ultralow frequency analogues of sound waves in Earth's magnetosphere play a crucial role in space weather, however, the public is largely unaware of this risk to our everyday lives and technology. As a way of potentially reaching new audiences, SSFX made 8 years of satellite wave recordings audible to the human ear with the aim of using it to create art. Partnering with film industry professionals, the standard processes of international film festivals were adopted by the project in order to challenge independent filmmakers to incorporate these sounds into short films in creative ways. Seven films covering a wide array of topics/genres (despite coming from the same sounds) were selected for screening at a special film festival out of 22 submissions. The works have subsequently been shown at numerous established film festivals and screenings internationally. These events have attracted diverse non-science audiences resulting in several unanticipated impacts upon them, thereby demonstrating how working with the art world can open up dialogues with both artists and audiences who would not ordinarily engage with science.

1 Introduction

Public engagement projects which see artists and scientists collaborate together in some way have become increasingly popular. Malina (2010) classifies such collaborations into the following categories:

- I. Scientists collaborating with artists on common projects resulting in both scientific discoveries and the production of art works
- II. Scientists applying scientific research to understand creative activity in the arts
- III. Scientists working with artists to develop technological inventions
- IV. Working as both a scientist and an artist in a dual career
- V. Scientists engaging with the arts to enhance cultural appropriation of science
- VI. Scientists engaging with the arts to improve the ways science is communicated to the public

At an art-science session at the 2019 Interact symposium (Archer et al., 2019) 12 university science researchers and public engagement professionals were surveyed for their attitudes towards art-science collaborations. This found that their interest in art-science collaborations were based on enjoyment of both subjects, utilising their creativity, and as a communication tool (particularly for different audiences). When asked who they thought the audience was for such collaborations: $67 \pm 17\%$ thought they are for everyone; $25 \pm 16\%$ said non-science arts audiences; and one person responded it depended on the aims of the project (see Appendix A for details of statistical techniques used throughout). Respondents thought art-science is important because it provides different ways of communicating science, can reach new audiences, can help embed science as part of culture, and that both disciplines can learn from one another through their respective creativity. Therefore Type VI of Malina (2010) was the most highly cited typology of art-science collaboration, though Types IV and V were also mentioned.

Engaging with new audiences seems to be a prominent motivation for scientists in undertaking art-science collaborations and many evaluations of art-science events have tried to assess whether they have indeed attracted non-science audiences. Science et Cité, a festival across 20 cities in Switzerland, while striving to be “a festival of the sciences and arts” attracted significantly more people who were interested by science ($40 \pm 1\%$) than art ($24 \pm 1\%$) (respondents could select from any number of 14 options), with the festival’s more art-themed events typically only attracting 1.4 ± 0.3 times more people with arts interests than science ones (von Roten and Moeschler, 2007). Another example — Covariance, a month-long art-science exhibit in London — found $95 \pm 1\%$ of their audience were frequent or occasional art goers and $83 \pm 3\%$ attended science events, hence there was substantial overlap in these two areas ($\geq 78 \pm 3\%$) (Lynch, 2013). Finally, the Art and Space exhibition in Dunedin, New Zealand attracted audiences $57 \pm 10\%$ of which had a professional background in the arts compared to $26 \pm 9\%$ in science, who primarily attended due to a general interest in art ($71 \pm 9\%$) rather than science ($38 \pm 9\%$) though $50 \pm 10\%$ were attracted by how science and art can combine (Brook, 2017). These case studies therefore highlight that art-science events vary significantly in their audiences’ interests and do not necessarily always attract new audiences as desired.

Given the multitude of different formats that constitute the art world, there are many ways of combining it with science. The twentieth century saw film emerge as one of the main art forms readily appreciated by the public (Nowell-Smith, 2017) and in recent years the film festival has burgeoned into an important area of cinema, both culturally and industrially, with an incredibly diverse range of festivals running internationally (Archibald and Miller, 2011). Research into film festival attendees (Báez and Devesa, 2014) has revealed three key motivating factors: “discovery”, “entertainment”, and “cinema”; with specialised film festivals (such as those covering specific genres, topics or issues) also providing a general feeling of belonging to a specific group and/or “cinephile community” (de Valck and Loist, 2009; Film Festival Research Network, 2019). Film festivals surrounding science have been growing in number (e.g. European Academy of Science Film, 2019; Imagine Science Films, 2019) with these typically featuring documentary films presenting scientific findings in an entertaining but still educational way. However, beyond simply improving the ways that science is communicated to the public (Type VI of Malina (2010)), there is the potential to as well have science appreciated more as part of culture via film (Type V). BIO-FICTION invites short films addressing current/future debate topics in areas of biology, with a near even mix of fiction and documentary style submissions (Schmidt et al., 2015). CineGlobe is a film festival at CERN which centres around broad and culturally relevant themes inspired by science and technology (CineGlobe, 2019). CineSpace is a film festival by NASA and Houston Cinema

Arts Society which solicits films inspired by and using actual NASA imagery. It was in a similar arena of cultural art-science that the SSFX (Space Sound Effects) Short Film Festival was devised.

2 Motivations

Space is far from completely empty, it's pervaded with very tenuous plasmas such as the solar wind that streams off of the Sun. Earth's intrinsic magnetic field acts as an obstacle to this wind and results in a magnetosphere, protecting us from much of this harmful ionising radiation. However, the interaction between the solar wind and the magnetosphere is highly complex and dynamic, resulting in phenomena which affect the space- and ground-based technology we increasingly rely upon in modern life such as electrical grids, GPS systems, and weather forecasts. These effects are known as space weather and have been recognised as a potential risk to our everyday lives (Cannon et al., 2013).

One way in which solar wind energy and momentum are transferred into and around magnetospheres are through plasma waves. The spatial and time scales where the weak plasma can largely be treated as a single conducting fluid dictated by magnetohydrodynamics necessitates plasma waves to fall within the ultra-low frequency (ULF) regime, with frequencies fractions of milliHertz up to 1 Hz. Of course this does not lie within the human auditory range, however, simply by dramatically speeding up playback of satellite observations it is possible to make our ULF wave measurements audible. Archer et al. (2018) converted perturbations in magnetic field data (which move similarly to the plasma itself due to the frozen-in condition within magnetohydrodynamics) taken at geostationary orbit into an audio dataset which is now publicly available from the National Oceanic and Atmospheric Administration (NOAA, 2018). This has already been used as tool in exploratory citizen science with schools, as detailed by the authors, but could lend itself to artistic uses also.

How this audible version of scientific data, or "sounds of space", could potentially be used in the creation of art was primarily informed by the sounds themselves. They surprisingly did not typically take on the musical quality somewhat expected by the researchers who study discrete frequencies and resonances within Earth's magnetosphere, but instead conveyed a sense of dynamism and variety as well as having a somewhat cacophonous nature. While the audible dataset described in Archer et al. (2018) was comprehensive enough in order to undertake science, for the purpose of creating art there was redundancy. Therefore to reduce the amount of data, only the time-differenced stereo summary files were used, averaging these over all spacecraft to result in only one audio file per year. Through an article in *The Conversation* (Archer, 2016), republished by *Newsweek*, *Daily Mail*, *Space.com* amongst others, online comments using SoundCloud on what people thought random periods of the data "sounded like" were solicited. While the accuracy and precision of SoundCloud comments' time-tagging meant it could not be used as a means of event identification for scientific research, it did result in the wide range of 85 unique responses (from 151 comments) that are shown in Figure 1. These reflections on the sounds planted the idea of their usage as sound effects in films, ultimately resulting in the SSFX (Space Sound Effects) Short Film Festival project. In the following sections we detail the various phases and audiences engaged through the project from filmmakers and exhibitors to film-goers, presenting findings on their motivations for getting involved and what impact the project had on them.

ever, we were challenging filmmakers to incorporate very specific elements, the provided sounds of space, into their work and
105 in many cases making a film especially for the festival. Given these unusual constraints, it was decided that we would try to
make the rest of the competition's criteria as broad and inclusive as possible. Therefore we would not charge a submission fee,
there would be no restrictions on genre or topic, we would allow filmmakers to modify the sounds as they saw fit, and permit
films created specifically for the competition or existing films edited to integrate the space sounds. The only other criteria we
set were by age and location, with categories initially for both UK and international filmmakers separately in the age ranges:
110 under 18, 18–24, and 25+. The significant work involved on the filmmaker side necessitated there being a large submission
window, which we set as six months long, which would hopefully provide enough time to produce high quality short films. We
felt it was important for there to also be monetary prizes associated with the competition, to ensure that filmmakers' efforts
were valued.

A website was established which hosted the space sounds for download, more information about the competition/festival,
115 and would post YouTube videos throughout the submission window providing more background on the science (SSFX, 2019).
However, it was deemed that using an existing online film festival submission platform would be better than coming up with
our own method. Desk research highlighted two portals — Withoutabox and Film Freeway (2019). We opted for the former,
given it was the first online film festival submission service and was owned by IMDB. In hindsight, however, we realised that
Film Freeway would have been more flexible. Withoutabox subsequently closed down in late 2019. While we had set our final
120 submission deadline, staff at Withoutabox recommended within their system that we have various different stages of deadlines
("early bird", "standard" etc.) since this would flag the opportunity to filmmakers looking at Withoutabox's upcoming deadlines
calendar. Finally, in order to reduce ineligible entries we asked that filmmakers provide some information on how they used the
space sounds. At first this was simply written in the terms and conditions to be included in their cover letter. However, it soon
became clear that many filmmakers were not reading the terms and simply submitting their ineligible films anyway. We were
125 able to get Withoutabox to add a custom required question which explicitly asked the filmmakers to provide this information,
which dramatically cut down (but did not entirely eliminate) spam entries. At this stage the competition was open and we
simply needed filmmakers to engage with the opportunity.

3.2 Engaging with filmmakers

To share the opportunity widely within the independent film community, existing networks were utilised: a protracted marketing
130 campaign throughout the submission window to Shooting People's over 45,000 member base was run through newsletters, an
editorial feature, and social media (Shooting People, 2019); flyers about the competition were mailed to every film school
in the country; we attended London-based filmmaker Meetup groups discussing the opportunity with around 70 filmmakers
(Meetup, 2019); and we contacted key people recommended by film industry judges for more grassroots marketing. As part
of formative evaluation to ensure these were being effective at reaching our target audience, we monitored the number of
135 people who registered interest in the project on our website (essentially subscribing to a mailing list) recording also their age,
location, and what their motivations for signing up were. In total 102 people signed up, after having discarded spam entries
(see later). The majority of people were 25 or over at $62 \pm 6\%$, with few under 18s at only $10 \pm 3\%$ (in hindsight perhaps

to be expected), which informed our merging of the two younger age categories in the competition early in the submission window. In terms of location there was an almost even split in absolute terms between those from London, elsewhere in the UK, and internationally, which is clearly unrepresentative of the global population and likely down to the main networks used to promote the opportunity.

To assess people's motivations we asked them to select from as many of the following options as applied: an existing interest in science generally (S), an existing interest in filmmaking (F), interest specifically in the project (P), or some other reason which they could then specify. We assume that all entries which did not select any of these options (including other) were spam. Sixteen people reported other reasons for registering interest (with three not selecting any of the main options): nine had a background in either sound design or musical composition; three were considering visualising the sounds; with others mentioning the creative challenge, interests in space or art-science, and the possibility of integrating the resulting films into existing science or art-science events. Figure 2 shows the breakdown over the three main options. The proportions in each set (i.e. S , F , and P) and region (of the Venn diagram) have been compared to those expected purely at random, with S , F , and $S \cap F$ being significantly greater than expected. We also compared the sizes of all sets and unions of sets with one another finding that most of these differences are statistically significant — of the 6 possible comparisons only S vs. F and F vs. $S \cup P$ were not. From this we deduce that people who registered interest typically had existing interests in both science and filmmaking. Given only small (typically only a few percent) fractions of the public work or have qualifications in film (e.g. BFI, 2019), we conclude that SSFX successfully engaged the filmmaking community. Given the considerable effort involved in creating a film, an interest in science also is thus understandable, though anecdotally from conversations with filmmakers it was found that their primary scientific interests (if any) were typically not in physics or space science though.

Leading up to the competition's deadline very few films had been submitted, therefore to assess this we sent out a survey to the mailing list six weeks before the deadline. While only seven responses were received, six indicated they intended to submit films though only two of these were confident that their film would be ready by the deadline. Based on these results we decided to extend the deadline by an additional two weeks to allow more time for filmmakers, while still having sufficient time for judging and event organisation. Even closer to the submission, a few filmmakers reached out stating that their films would not be complete so we took the decision to allow work in progress submissions, so long as the filmmakers indicated what additional work needed doing and that it could be achieved in time for the event.

3.3 Evaluating film submissions

By the deadline 22 eligible films had been submitted (180 ineligible films not featuring any space sounds were also submitted, most of which came before the bespoke question was implemented), which according to their credits involved a total of 90 people. These films themselves demonstrate an impact on filmmakers, given that they have engaged with an opportunity to co-create an art work based around scientific data — a substantial undertaking. Most entries (nine) were in the 25+ UK category with 4–5 entries in the other three categories. This also meant that most entries came from the UK ($59 \pm 12\%$) though we note international filmmakers from Brazil, Canada, Italy, Portugal, and USA also submitted films. None of the differences in submission numbers were statistically significant by category, age, or internationality.

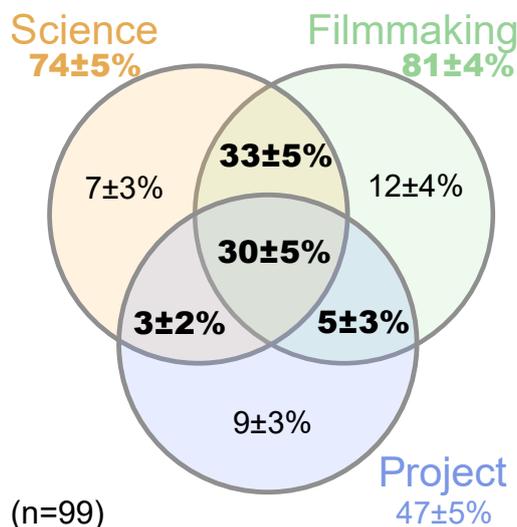

Figure 2. Venn diagram of people’s reasons for registering interest with SSFX. Bold values denote statistically significant differences from pure randomness (expected 57% in each overall set, 14% in each region) taking into account multiple comparisons ($\alpha_{Bonf} = 0.017$ for sets and $\alpha_{Bonf} = 0.0071$ for regions). Created in part using InteractiVenn (Heberle et al., 2015).

Each film was scored by the judges on both their usage of the space sounds (e.g. a few submissions had just a token usage of the sounds within their films) and overall impression of the film with equal weighting within Withoutabox’s online system. Judges could also leave any written feedback on both judging criteria to help final decisions. A subset of all the submissions based on total runtime were assigned to each judge, though 11 films were seen by all judges (the shortest ones) and at least 3 judges saw each submission. One of the film industry judges noted “*The process of running the competition was extremely professional and I would recommend the model to others in the future, with a secure screening system, showing full creative credits for each film that allowed feedback to be added and votes cast within one dedicated site. Thanks for such great organisation and clear steer on how you wanted the judging to go.*” In the end there was a fair amount of disagreement between the judges — the alpha coefficient of Krippendorff (2018) for these ordinal measurements was only 0.43. Each judge’s scores were therefore standardised, using means and standard deviations across only those films which were seen by all, to ensure no one judge had more sway in the outcome. Given the overall time within the venue we were able to select the top eight films (based on the average standardised scores) for exhibition, however, one of these was unfinished upon submission and could not ultimately be completed in time. This film dropping out necessitated merging the two international categories.

One of the film industry judges noted about the submissions “*I was really impressed by the quality and diversity of films submitted through the competition as well as the international uptake. The range of film making styles was really interesting, there were dramas, comedies, animation, science fiction and avant-garde productions with some films exploring the scientific concepts directly and others using them in more abstract ways... I really loved the fact that the project was open in how filmmakers could interpret the sounds in their productions and I think this was key to gaining the variety that appeared across*

190 *the submissions.*” We note that even while some of the films incorporated elements of the underlying scientific concepts, they were not the primary focus of the films and were done in creative fictional ways and not in a documentary style. Thus all the films fell under the “science as culture” type of art-science, i.e. Type V of Malina (2010), rather than a form of direct science communication (Type VI). Even one of the judges noted “*it has genuinely got me thinking about how I could explore some of the research in my future creative outputs*”. The conclusion from these is that by giving a huge amount of creative freedom
195 over to the filmmakers in allowing them to interpret and include this scientific data as they saw fit, it enabled the creativity and variety of films submitted, thus highly aligning with the aim of integrating science into culture. The following sections summarise the selected works, including the filmmakers’ reflections.

3.3.1 Astroturf

Synopsis: A meticulous young man tends to his fake garden to the sounds of deep space

200 Genre: Science Fiction

Duration: 1 min

The film depicts a man performing gardening tasks, though this garden features no real plants instead being filled with the titular astroturf along with plastic flowers, trees, butterflies etc. It is revealed at the end that this garden is on the moon and that the Earth is on fire. The director noted “*We wanted to make a film that used the space sound effects in an interesting way, while telling a compelling short science-fiction story. The rustling, swirling space sounds reminded us of the noises that people make all the time when performing simple tasks - sounds that in film are often replaced or reproduced as foley. So we decided to build the entire soundtrack from the space sound effects, and created a simple narrative that involved a combination of actions that we felt would be convincing when dubbed. We came up with the idea of putting it in space because of the space sounds... Because [in the film] we’ve screwed up the Earth, for him this tiny patch of land is extraordinarily precious and so*
205 *that was where his character emerged from.*” The producer added “*He’s trying to recreate what he’s known in the past, what a real garden is, in this fake world that he’s living in. Because we’re both ‘greenies’ and we see that as a potential future for us, that was what really inspired that incongruous nature of nature versus fakeness.*” Further comments can be found at <https://www.youtube.com/watch?v=RpC-sFzUnEE>.
210

3.3.2 Dark Matter(s)

215 Synopsis: An experimental and meditative imagining capturing the activities of a fish tank in a way that takes the inhabitants out of their enclosed world, to a place unknown, to feel both their death and their life.

Genre: Video Art

Duration: 5 min

The director describes the film as “*about a couple fish in a fish tank, but we tried to film it in a way that it doesn’t look like they’re in a fish tank... that got rid of the boxed in enclosure. When I realised what’s bigger than being a locked in a box was everything, it made such sense to me to look into sounds from space. I think the sound from space gives it that extra push for [the fish] to like break out of this cage or for that dichotomy of inside versus outside to be transcendent. As soon as I figured out*
220

that I was going to use sound effects from space I think the project came full circle.” The sound designer commented on how he modified the sounds for the film, which were matched with classical music throughout: “I used a lot of reverbs to soften
225 them [the sounds], I did a little bit of slow panning, I shifted the pitch on the sound effects a couple times to separate them, I shifted them down to make them a little deeper. There’s this one part where there’s a bunch of bubbles and so I changed them so they could sound like bubbles. Basically the whole process was making them soft enough to fit in the context of the film.” Further comments can be found at <https://www.youtube.com/watch?v=quLaFmS9kDE>.

3.3.3 Murmurs of a Macrocosm

230 Synopsis: A journey through a microscopic world. We are led via the descriptive recordings of those who travelled it.

Genre: Science Fiction

Duration: 5 min

This film shows recoloured drone footage from Snowdonia paired with NASA Apollo recordings and the space sounds to depict exploration in a microscopic realm, which is revealed at the end to be inside the grooves of a vinyl record of the moon
235 landings. The filmmaker stated “It was a visual that I always loved to, those SEM microscopic images that are colourised black and white images. But I always wanted a little bit more, I wanted to move around them. I think when hearing those sounds it kind of reminded me a bit of a record player. It also reminded me a lot of the sound from space in ‘Contact’, the Carl Sagan film / book, that’s how it came together from those little things.” When discussing how the use of NASA recordings he noted “finding this sort of innate humour and human conversation that they would often have to each other and they just felt so in
240 awe the whole time... they’re constantly excited which I really love that aspect of exploration.” Further comments can be found at https://www.youtube.com/watch?v=e3kUGlVI_Hk.

3.3.4 Names and Numbers

Synopsis: A sound and voice collage shaped by the sounds of space and Morse code, addressing the external, physical and material experiences of sound and movement contrasted with interior reflections, explored through language, inner voices and
245 symbols.

Genre: Experimental

Duration: 14 min

The filmmaker explained how this experimental piece came together: “I tried to enact that experiment of writing down your thoughts to the sound of a buzzer which samples your mind at any particular time... It was basically an accumu-
250 lation of ideas and just sitting down and following the logic of each individual material thing: a soundtrack, recording a piece of text, a collection of different images. There was no simple way of putting them all together and I guess the stream of consciousness of that writing process was one of the guiding principles.” Further comments can be found at <https://www.youtube.com/watch?v=Uuvcm1YfdZ4>.

3.3.5 Noise

255 Synopsis: A secretive woman opens herself up to her unruly housemate, after they are stuck together in her room.

Genre: Drama

Duration: 13 min

This drama film is about a woman who often isolates herself by listening to the sounds of space, and who doesn't get along with her very different housemate. They eventually are able to connect over these sounds. The director noted on the title "*noise is a specific scientific term for something which has no informational value... and so when the characters are talking to each other they're trying to work out what's noise and whether they can actually understand anything from what they're saying to each other... Once you heard the sounds they kind of wrote the story, they had to carry the narrative, creating a character in and of themselves.*" Further comments can be found at https://www.youtube.com/watch?v=Fgvo_IP7ZmA.

260

3.3.6 Saturation

265 Synopsis: There's no answer when time is the question. Featuring 35mm slides found in a medical archive, this sci-fi story concerns unknown phenomena that made all organic processes so fast as to make life impossible.

Genre: Science Fiction

Duration: 7 min

This film couples still images of medical imagery with subtitled text and a soundtrack composed of modified space sounds. The filmmaker explained the creative process "*When I first started to edit the film a couple of years ago, before I even knew what it was supposed to be, I thought [the mysterious phenomenon in the film's narrative] was something related to space... When I saw your call [for films using the sounds of space], I realised that's what I needed - something really from space that I can use on my film. To make the sounds more tense I saturated them, making them more drone-like... I was also interested by the process itself of making the sounds hearable by stretching and compressing the time and it is very related to the narrative that I was thinking.*" Further comments can be found at <https://www.youtube.com/watch?v=rYxFHEXQ4aQ>.

270

275

3.3.7 The Rebound Effect

Synopsis: Bringing together contemporary movement and digital media to capture dance in a way which pushes beyond the tangible dimensions of live performance.

Genre: Dance / Music Video

280 Duration: 2 min

This film depicts a modern dancer moving to the sounds from space mixed with electronic music. Unfortunately filmmaker comments about this work were not captured.

Figure 3. Photos from the SSFX Short Film Festival. (Top) Presentation about the underlying science. (Bottom Left) Panel discussions between scientists and filmmakers. (Bottom Right) Awarding of prizes to filmmakers.

3.4 Running a film festival

A boutique arts and cinema venue was hired for the SSFX Short Film Festival (Rich Mix in Shoreditch, London). To capitalise on their regular members, we opted to have them host ticket sales and primarily undertake marketing for the event. While the event was not being run to make a profit, we decided to charge a small ticket price to reduce cancellations and convey a sense of perceived value for the event. In reality all ticket proceeds actually went into the cost of a free post-event reception. The cinema required the films in a digital cinema package (DCP) format. First we received the high-quality video files from the selected filmmakers and then converted these using the free open-source DCP-o-matic (2019) software. For exhibition to the public the films required British Board of Film Classification (BBFC) certification also, which were submitted as DCPs online. The majority of classifications were Universal rating bar two — one was deemed Parental Guidance for “mild surgical detail” and another gained at 15 rating due to “strong language and drug misuse”.

The event was started with an unadvertised short presentation on the underlying science to the audience. These were then followed by groups of film screenings, awards presentations, and panel discussions between scientists and filmmakers (inter-

295 national filmmakers joined via video conferencing) about their work and approach to the project. Photos of all of these can
be seen in Figure 3. The post-event reception then enabled further discussion between scientists, filmmakers, and film-goers.
Evaluation of this event (and subsequent ones) can be found in sections 4 and 5.

3.5 Supporting the films and filmmakers

Following the SSFX Short Film Festival, we wanted to support the filmmakers in sharing their work more widely. In return
300 we asked them to add specific prologue/epilogue text about the underlying science as well as items in the credits pertaining
to project staff, data providers, and funders. In hindsight, it may have been easier to ask for this at the selection stage so these
would have been incorporated into the high quality versions provided for the festival.

There were a number of different ways in which we supported the filmmakers. Firstly at the level of individual films we
financed the top four highest scoring films' submission fees to existing UK film festivals, as this was flagged by the filmmakers
305 as a limiting factor in their ability to share the work more widely. We left it up to the filmmakers to determine which festivals
might be the best fit for them given the budget offered to each. Secondly, we acted as champions representing the entire set
of shorts, approached numerous film exhibitors to enquire about some of them being considered for screening within their
existing events. Finally, we wanted to offer the entire set of shorts as a ready-made package that could be screened elsewhere.
However, it was deemed that simply showing the shorts back-to-back and not also having some background to their context and
310 production would not be such an informative nor entertaining experience for audiences. Therefore, it was decided to produce a
framing film which would incorporate the shorts into an anthology.

A tender was put out to various production houses and through networks soliciting pitches for this framing film. The aim
was that this framing film could in a narrative way bridge together the short films while also communicating a few simple
messages about the underlying science behind the space sounds and how they affect us. We received three proposals, which
315 were very different in approach. We went ahead with one which envisioned a point-of-view shot film during a space weather
event, where technology failing causes the films to appear on various screens around the house. We worked closely with the
production company on the development of the script and through the production process. The poster for the anthology film,
composed of imagery from the individual short films, is shown in Figure 4. This anthology was released for free on YouTube
in October 2018 (https://www.youtube.com/watch?v=P5_OljSnA1k).

320 Overall, the filmmakers were very grateful for all the support offered. One of the filmmakers noted "*The SSFX project was
incredibly rewarding and allowed us as a creative team to learn about an exciting area we had no knowledge of previously.
We also met other interesting filmmakers and found the audiences incredibly engaged and interested into the background of
the project and where the research is. We have had a lot of positive feedback and have been able to direct our audiences to
the SSFX website for more information. Martin Archer has been incredibly supportive and a champion for these films, for
325 which we are incredibly grateful and have found invaluable.*" Another said "*Collaborating on the project was a wonderful
experience and we were so grateful for all the opportunities offered to our film from taking part, reaching an international
audience with our film and getting to enter into dialogues with audiences, scientists and other filmmakers. If it wasn't for
SSFX, I'm not sure that our production team would have thought to engage so thoughtfully with sounds from space – we didn't*"

Figure 4. Anthology film poster composed of imagery from each of the selected shorts.

330 *know they existed. Not only did Martin provide exceptionally unique and compelling sounds for any sound designer to work with, but he was so thoughtful in terms of explaining the science and techniques used to capture these sounds. As someone who was a little intimidated by science in school, I really felt an understanding around the basic mechanisms and significance around obtaining these compelling sounds. As a filmmaker, I appreciated this so that I could answer questions at Q and As with confidence and ease. One of the other aspects about this project that I appreciate was Martin's ability to have people from all over the world join in on the conversation. Multiple times throughout this process, I was able to talk to audience members and fellow filmmakers on a different continent while staying in the US. This is not something that I've experienced a lot in the independent film festival world. If you can't physically attend, then you simply can't be a part of the conversation. That was not the case with SSFX and it made the experience all the more educational, inclusive and fun for everyone involved."* These comments highlight the impact that the open, collaborative and supportive approach that SSFX took had on the filmmakers.

335

4 Infiltrating film events

340 Several complementary approaches were taken to get the SSFX films more widely seen as part of film festival and events programmes. As noted earlier, we paid the submissions fees for film festivals (limited to the UK only due to funding usage restrictions) identified by the filmmakers. In addition to this, we advertised the free shorts and/or anthology through film exhibitor networks recommended by our judges (including the various BFI Film Audience Network hubs and the Independent Cinema Office) and approached several key film exhibitors, enquiring about either arranging one-off screenings of the anthology or showing the shorts before their features. This generally fed into their aims of developing audiences for and increasing access

345

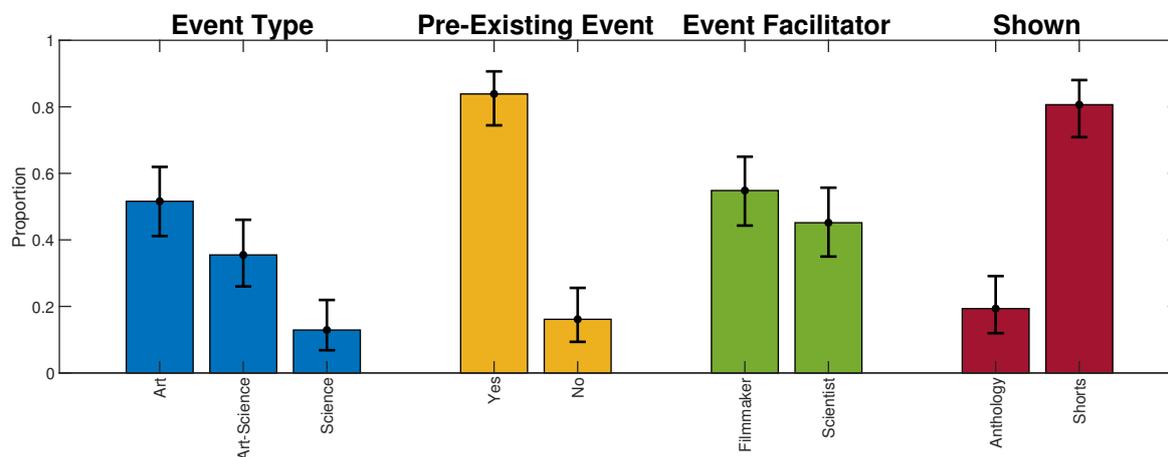

Figure 5. Summary statistics of SSFX events.

to a diversity of film content for local independent film-going communities. We also liaised with a few science focused events such as science festivals, either through open calls or those that approached us, about integrating the films into their programme in some way.

Table 1 details all the events which featured SSFX film screenings, where these have been grouped by initiative since in several cases multiple screenings of the same or different films occurred. There was a large overrepresentation of UK-based events ($68 \pm 10\%$) compared to all film festivals globally (8% , $p = 3.5 \times 10^{-17}$) as listed in Film Freeway (2019). This was in part due to funding usage restrictions limiting which festivals could be applied for, however, we also note that many film festivals aim to highlight the works of filmmakers from their own country.

Events have been classified as either art, art-science, or science, with the distribution of event types shown in Figure 5. Art events denote those with no clear association with science whatsoever, science events indicate those with no explicit link to art, and art-science is used to describe events with a stated connection between the two subjects. There were substantially more art events than science ones ($p = 0.012$, $\alpha_{Bonf} = 0.017$), which constituted the only significant difference between SSFX event types. Excluding science events, art-science ($41 \pm 11\%$) was overrepresented compared to all film festivals globally that contain some mention of space or science (11% , $p = 6.1 \times 10^{-5}$). Both of these results reflect some of the struggles faced in the second phase of the SSFX project — science event programmers were largely uninterested in art-science since their audiences are already highly engaged with science and not necessarily with art, whereas many film event programmers we approached struggled to understand the concept of the project thinking the films were aimed at science audiences rather being open to judge them as films in their own right that happen to contain a scientific connection (i.e. their preconception was Type VI of Malina (2010) rather than Type V).

Figure 5 demonstrates that screenings predominantly occurred as part of pre-existing events rather than at bespoke ones ($p = 1.9 \times 10^{-4}$), indicating SSFX was largely successful at infiltrating science into the film world, and there was a fairly even split in events arranged by filmmakers or scientists. We note that filmmakers were more successful at infiltrating art events

Table 1. List of SSFX events. Asterisks denote estimated audience figures due to lack of information from event organisers.

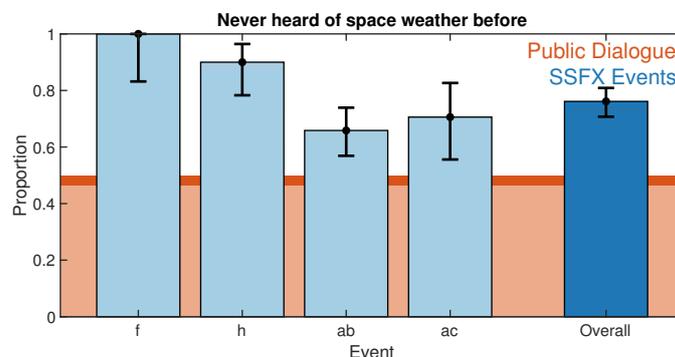

Figure 6. Prior knowledge of audience at SSFX art-science events in blue compared to a recent public dialogue (3KQ and Collingwood Environmental Planning, 2015) in orange.

($71 \pm 14\%$ of all their events) than the scientist ($29 \pm 15\%$), though this difference was not strictly statistically significant when accounting for multiple comparisons ($p = 0.021$, $\alpha_{Bonf} = 0.017$). Primarily it was an individual short film or subset of the collection of shorts which was exhibited at events rather than the full anthology film ($p = 8.8 \times 10^{-4}$), which we struggled to convince film programmers to incorporate into events despite advice from film industry collaborators that this might be an attractive proposition.

Film festival acceptance rates are typically $\sim 5\%$ (Stephen Follows, 2013b) with the largest festivals being $\lesssim 1\%$ (Sponring and Puskás, 2018). While we do not have concrete numbers on exactly how many festivals the filmmakers submitted to, given the budget and average submission cost for short films (Stephen Follows, 2013a) we estimate around 30 total submissions. This means that the 17 festival successes constitutes an impressive acceptance rate across the shorts of $57 \pm 11\%$, significantly higher than expected. This perhaps reflects the quality of the art-science films that resulted from the project. We also note that given the filmmakers were submitting their shorts to festivals independently and all found success, this lends confidence beyond just an individual case study that this model of infiltrating science into cultural events can indeed work.

380 5 Engaging audiences through film

We generally relied on the event organisers to attract audiences, since they have built-in audience bases from their previous activities. Given we were largely infiltrating existing events, this limited the evaluations that could be implemented especially as at many events (especially the international ones) no filmmakers or scientists from the project were physically present. Therefore, evaluation data was typically collected only at bespoke SSFX events and several methods were employed: ball and bin questions upon arrival assessing prior knowledge, graffiti walls at post-film receptions assessing their motivations and takeaways, and an online survey three weeks later for those who left contact details. Filming by a third party at the SSFX Short Film Festival (event ab) captured additional qualitative data.

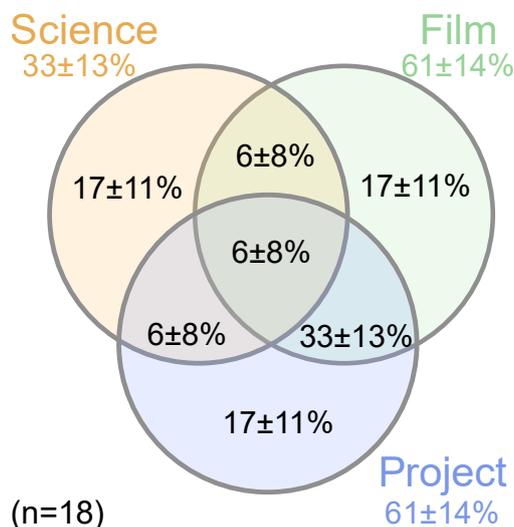

Figure 7. Venn diagram of people’s motivations for attending SSFX art-science events in the same format as Figure 2.

As part of a recent public dialogue, 3KQ and Collingwood Environmental Planning (2015) found in a survey of 1,010 people representative of the UK adult population (by gender, age, social grade, education, dependants, geographic region, and human settlement type) that a large fraction ($48 \pm 2\%$) have never heard of space weather before. The results from the individual events where we asked this question of attendees before the films (via a ball and bin method) are displayed as the light blue bars in Figure 6 indicating levels greater than this. Combining the data from all these events gives an overall result (dark blue) of $76 \pm 5\%$, which constitutes 2.95 ± 0.20 times more likely (the odds ratio) to have never heard of space weather than the general population ($p = 9.2 \times 10^{-8}$). Therefore an atypical audience was attracted to these events in terms of prior knowledge. Note that these results came exclusively from art-science events and arguably one might expect an even greater overall proportion of people to be unaware of the field at the art events that SSFX infiltrated.

Another way we assessed whether the project attracted new audiences was by asking what motivated them to attend. At two art-science events (ab and ac) this was collected via open-ended graffiti walls, where 9 responses were recorded. Through thematic analysis it was possible to group all of these as being due to an interest in science (e.g. “love science”), film (e.g. “I like weird films”), or specifically the project (e.g. “interesting concept”). Follow-up online surveys after several events (f, h, aa, ab, and ac) specifically asked whether attendees had been attracted due to regular attendance at science events, film events, or if it was specifically this event that had interested them. Given this yielded only 12 responses we opt to combine the data from both methods, omitting event aa since out of those events surveyed it was the only science event as well as the only pre-existing one. The overall results are shown in Figure 7. Repeating the same analysis as with filmmakers’ motivations revealed that significantly more people attended due to being film-goers or specifically being interested in the project ($F \cup P$) at $78 \pm 12\%$ compared to attending science events often (S) at $33 \pm 13\%$ ($p = 0.0023$, $\alpha_{Bonf} = 0.0083$). This therefore provides further evidence that SSFX was able to attract substantial non-science audiences, placing it as comparable to some of the most

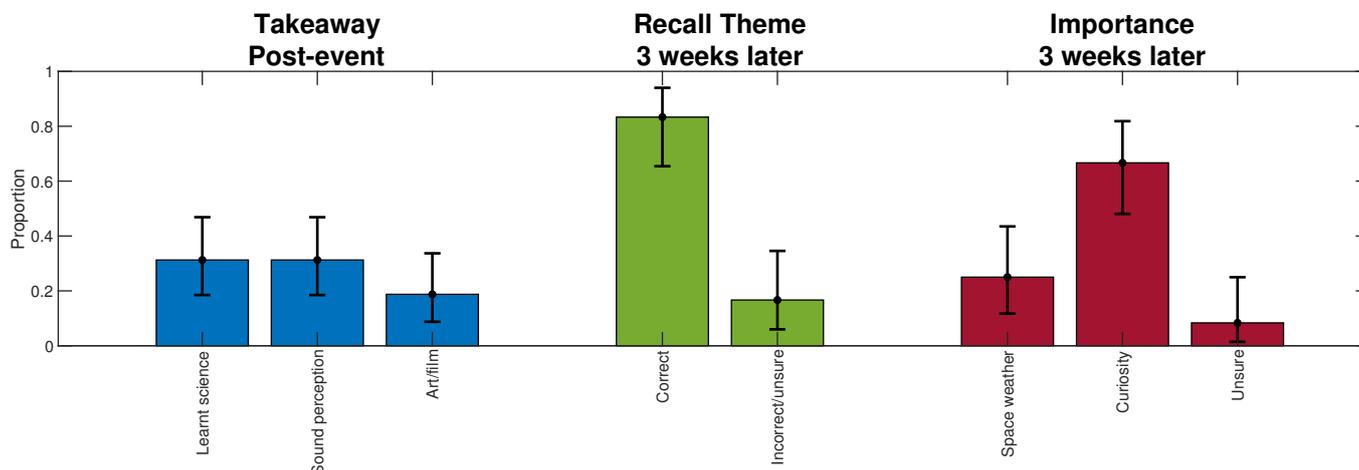

Figure 8. Summary statistics of evaluation data following SSFX events.

successful art-science events across different art forms at reaching new audiences (cf. Brook, 2017). Again we note that since this analysis pertained only to art-science events, it is highly likely at the art events SSFX infiltrated that even fewer people would have exhibited science interests given the complete lack of a science-connection at these events and the existing research into the motivations behind film festival attendance (Báez and Devesa, 2014).

We assessed the learning outcomes of attendees through the follow-up surveys, asking in open questions if they recalled the event's theme and why this topic is studied/important. As shown in Figure 8, the majority ($83 \pm 14\%$, $p = 0.039$) correctly recalled that the event concerned the sounds of space or provided more specific answers. Interestingly most ($67 \pm 17\%$) thought this area was important due to the inherent value of science / intellectual curiosity (e.g. "It helps us to understand the universe, physics, and gives us a clearer idea of the world around us") rather than citing space weather ($25 \pm 16\%$), though this majority was not statistically significant and neither were the differences between responses. As far as we are aware there is little published research into the recollection of public engagement events' themes and key messages by attendees in follow-up surveys. However, comparing with studies into the recollection of television campaigns (e.g. Berry et al., 2009; Potter et al., 2019) and the so-called Memory Chain Model (Murre and Dros, 2015) suggests that the fraction quoting space weather would be deemed successful, while the recollection of the event's overall theme would be considered extremely high. Also, given the atypical non-science audience, the fact that many attendees took away from the event the value of fundamental scientific research was an unanticipated but very welcome impact.

In terms of impact on attendees, at two art-science events (ab and ac) we asked via graffiti wall what (if anything) they had gained or taken away from the event. Most of the 16 responses could be broadly categorised as concerning the science (e.g. "amazing space sounds I want to learn more about"), perception of sound (e.g. "people hear differently"), or art/film (e.g. "grown an interest in film-making"), with the proportions of each shown in Figure 8 demonstrating a near even split between the three. Other miscellaneous takeaways included aspects of science communication, humanity, and specific (non-science) themes raised in the films. Furthermore, at the SSFX Short Film Festival (event ab) a selection of people were interviewed

430 during the reception by a third party. The most common point that emerged was that attendees really enjoyed the broad range
of interpretations of the same space sounds which were expressed in the different films. Others commented on how the concept
of the festival was an interesting approach of bringing scientific ideas to a wider audience, that they had learned about and
gained an interest in the science behind the sounds, and that it attracted a diverse group of people with a lot of interaction
particularly in the reception. On this latter point, it was anecdotally noted at most of the events that the diversity of audiences
435 by gender and ethnicity appeared much greater than compared to typical physics engagement events, though this was not
captured quantitatively. Respondents in the follow-up survey also noted other takeaways from attending: enjoying or being
inspired by the event (e.g. *“Really enjoyed the enthusiasm of the speaker and the topic of the films mixed with science”*),
the creativity/diversity of films (e.g. *“how each filmmaker found the humanity in sounds from space”*), meeting and hearing
from both scientists and filmmakers (e.g. *“It was interesting to meet some of the people involved in both the science and
440 filmmaking”*), developing an interest in arts events (e.g. *“I will definitely look at the [arts venue] Rich Mix website more
for future events”*), and the importance/relevance of the scientific research (e.g. *“Genuine and relevant science research and
knowledge is vital and underused in the film industry”*). One respondent wrote in detail: *“Taking raw data out of context
and using it as a key creative element in the creation of art is a way of providing a fresh look at a scientific inquiry. Art can
be a mirror whose reflection can reset context and provide the listener with a different perspective than might otherwise be
445 encountered. The result of this competition has been a number of submissions that stimulate a wider audience to think about
how science is more than just the collection of raw data, and that understanding can come from looking at results from a new
vantage.”* All these results highlight that there were many unforeseen impacts upon attendees outside of simply raising awareness of
the research area to atypical audiences.

6 Conclusions

450 The SSFX (Space Sound Effects) Short Film Festival was an art-science collaboration project aimed at infiltrating space science
into culture through the medium of film. In particular it invited the usage of sonified satellite data of plasma waves in Earth’s
magnetosphere, a key component within space weather, as key creative elements.

The first audience the project aimed to engage were independent filmmakers through challenging them to use these space
sounds to create short films. Through partnership with film industry experts and organisations, an international film festival
455 was run adopting many of the standard practises within the sector to lend authenticity and legitimacy to the project. Formative
evaluation of people who registered interest with the project during the submission revealed that we successfully hooked the
filmmaking community, though most who engaged also had a general interest in science. Seven very different films were
selected for screening. Feedback from these filmmakers highlighted that they relished the creative freedom afforded to them in
interpreting the sounds and their usage within their works, hence very open criteria are not only enticing to filmmakers but also
460 enable a broad range of art works to be produced. Another important aspect to the project was in supporting the filmmakers and
championing their films after the initial festival, which had the mutual benefit of raising the profile of the filmmakers whilst
also sharing the underlying science more widely.

The second audience was film programmers and exhibitors in trying to infiltrate the produced short films into existing events. While an anthology film packaging all the shorts together through a science-based narrative was produced, we struggled to get
465 this shown and found much greater success with the individual short films. Filmmakers were best placed to submit their own works to film festivals following the standard method, with monetary support from the scientists, as they have a better idea of which festivals would be most appropriate. However, scientists were still able to play a role in representing the full suite of shorts for consideration at other sorts of film events. Both of these approaches led to SSFX infiltrating more art events than science ones, as desired, though a substantial number of art-science events also occurred.

470 The project ultimately also aimed to raise awareness of the science to atypical audiences through the use of the films. While audience evaluation proved challenging due to SSFX films typically sitting within larger events organised by others, some evaluation was able to be done at mostly bespoke art-science events. This highlighted that attendees were much less aware of the topic of space weather than the general public and were much more likely to have attended due to an existing interest in film or specifically the concept of SSFX rather than having an existing science interest. This placed the project as comparable to
475 some of the most successful art-science events across different art forms at reaching new audiences. Many different, and often unanticipated, impacts were had on attendees beyond simply learning about the science, which demonstrates the versatility of film as a form of art at provoking varied responses in audiences.

We therefore advocate that adopting a film festival model can result in creative art-science that fits within the many film-based cultural events around the world. This enables the power of cinema to be leveraged on audiences that don't normally
480 engage with science, thus providing one potential means of breaking beyond the scientific "echo chamber" in perveying the importance and relevance of scientific research.

Appendix A: Statistical techniques

Several statistical methods are used throughout this paper which are detailed here.

All uncertainties quoted or displayed, e.g. through errorbars, represent standard (i.e. 68%) intervals. For proportions/probabilities
485 these are determined through the Clopper and Pearson (1934) method, a conservative estimate based on the exact expression for the binomial distribution, and therefore represent the expected variance due to counting statistics only and not any other potential sources.

Several statistical hypothesis tests are used with effect sizes and two-tailed p -values being quoted. Throughout the desired significance level α is set as 0.05, though in the case of multiple comparisons we use the Bonferonni correction where the
490 significance level per comparison is $\alpha_{Bonf} = \alpha/N$ for N total possible comparisons. Two-tailed binomial tests are used to compare proportions of both independent and correlated (i.e. within the same) samples.

Data availability. The data will be made available.

Author contributions. MOA conceived the project and its evaluation, performed the analysis, and wrote the paper.

Competing interests. The author declares that they have no conflict of interest.

495 *Acknowledgements.* We thank the SSFX Short Film Festival judges Laura Adams, David Berman, Ed Prosser, and Jake Roper; the selected filmmakers Adam Azmy, Victor Galvão, Nidhi Gupta, Aaron Howell, Ali Jennings, Simon Rattigan, Jesseca Ynez Simmons, and James Uren; and all the film industry experts and exhibitors that helped us share this work with audiences. This project was supported by a QMUL Centre for Public Engagement Large Award, EGU Public Engagement Grant, and STFC Public Engagement Spark Award ST/R001456/1.
