8 **Abstract**

9 Hydraulic fracturing, or fracking, is a borehole stimulation technique used to enhance permeability in
10 geological resource management, including the extraction of shale gas. The process of hydraulic fracturing
11 can induce seismicity. The potential to induce seismicity is a topic of widespread interest and public
12 concern, particularly in the UK where seismicity induced by hydraulic fracturing has halted shale gas
13 operations and triggered moratoria. Prior to 2018 there seemed to be a disconnect between the
14 conclusions of expert groups about the risk of adverse impacts from hydraulic fracturing induced
15 seismicity, and the reported level of public concern about hydraulic fracturing induced seismicity. Further,
16 a range of terminology was used to describe the induced seismicity (including tremors, earthquakes,
17 seismic events, and micro-earthquakes) which could indicate the level of perceived risk. Using the UK as
18 a case study, we examine the conclusions of expert-led public-facing reports on the risk (likelihood and
19 impact) of seismicity induced by hydraulic fracturing for shale gas published between 2012 and 2018 and
20 the terminology used in these reports. We compare these to results from studies conducted in the same
21 time period that explored views of the UK publics on hydraulic fracturing and seismicity. Further, we
22 surveyed participants at professional and public events on shale gas held throughout 2014 asking the
23 same question that was used in a series of surveys of the UK publics in the period 2012 – 2016; “do you
24 associate shale gas with earthquakes?”. We asked our participants to provide the reasoning for the answer
25 they gave. By examining the rationale provided for their answers we find that an apparent polarisation of
26 views amongst experts was actually the result of different interpretations of the language used to describe
27 seismicity. Responses are confounded by ambiguity of language around earthquake risk, magnitude, and
28 scale. We find that different terms are used in the survey responses to describe earthquakes, often in an
29 attempt to express the risk (magnitude, shaking, potential for adverse impact) presented by the
30 earthquake, but that these terms are poorly defined and ambiguous and do not translate into everyday
31 language usage. Such “bad language” around fracking has led to challenges in understanding, perceiving,
32 and communicating risks around hydraulic fracturing induced seismicity. We call for multi-method
33 approaches to understand perceived risks around geoenery resources, and suggest that developing and
34 adopting a shared language framework to describe earthquakes would alleviate miscommunication and
35 misperceptions. Our findings are relevant to any applications that present - or are perceived to present -
36 risk of induced seismicity. More broadly, our work is relevant to any topics of public interest where
37 language ambiguities muddle risk communication.

38

39 **1. Introduction**

40 Shared decision-making on complex sociotechnical issues such as climate change requires effective
41 dialogue between stakeholders, including academics, regulators, industry, policy makers and the publics.
42 However, clear communication to support effective dialogue presents challenges. Geoscience topics can

43 face particular communication challenges for several reasons. First, geoscience underpins many issues of
44 environmental and societal importance, such as resource development (water, energy resources) and
45 understanding and mitigation of climate change. These issues are not only important for future
46 generations, but associated activities (e.g. resource extraction, development of low-carbon energy
47 projects) have direct and indirect socio-economic and environmental impacts at a range of scales (Leach,
48 1992; Vergara et al., 2013; Adgate et al., 2014; Stephenson et al., 2019). Secondly, many geoscience
49 concepts and technologies, as well as the geological resources that modern lives depend on, are uncertain
50 or unfamiliar to the wider public. This is complicated by the fact that the Earth's subsurface is by nature
51 both heterogenous and largely inaccessible. Amongst geoscientists, uncertainties around, for example,
52 geological heterogeneity, affect the confidence of predicted geological properties or structure (Lark et al.,
53 2014; Bond, 2015) and can lead to differing interpretations of the subsurface (Bond et al., 2007; Alcalde
54 et al., 2019; Shipton et al., 2019) - even scientific dispute (compare interpretations of the N. Sea Silver Pit
55 Crater (Stewart and Allen, 2002; Stewart and Allen, 2004; Underhill, 2004) or causes of the Lusi Mud
56 Volcano (Mazzini, 2018; Tingay et al., 2018)). Thirdly, the inaccessibility of and general unfamiliarity with
57 the subsurface can make it challenging for lay publics to conceptualise it (Gibson et al., 2016), and
58 particularly to conceptualise geological processes or climate and engineering risks (Taylor et al., 2014).
59 Finally, geoscience terminology is often ambiguous, incomprehensible for many outside – and within –
60 the discipline, or has multiple meanings. As an example, it is common to use ambiguous phrases or
61 descriptors such as 'deep' in the Earth, 'low levels' of contaminants, a 'large' fault, or 'geological
62 timescales'. Even the technical language used to describe geological observations can imply a specific
63 conceptual model or processes, or have slightly misleading meanings relating to the outdated origins of
64 the word, both of which can lead to miscommunication amongst geoscience experts (Shipton et al., 2006;
65 Bond et al., 2007). One of the key findings of this paper is that language ambiguity around earthquakes
66 presents challenges for geoenergy decision-making.

67 Stakeholder perspectives have diverged on technical issues such as geological risk or environmental
68 impact of geological disposal of radioactive waste (Vander Becken et al., 2010; Lowry, 2007), shale gas
69 (Graham et al., 2015), and urban planning (Marker, 2016). Hydraulic fracturing (often referred to as
70 'fracking', sometimes spelt 'fraccing' or 'fracing') for shale gas presents one such high-profile example.
71 Here, we explore the perception of, and terminology around, the risks (likelihood and impact) of induced
72 seismicity presented by hydraulic fracturing for shale gas in the UK context. This work is timely: how we
73 use the subsurface is changing as we transition to a low-carbon economy; new technologies and new ways
74 of using the subsurface are anticipated in coming decades (Stephenson et al., 2019) and there is a clear
75 need for further social scientific insights to inform risk management and communication around
76 geoenergy-induced seismicity (Trutnevyte & Ejderyan, 2018).

77 To frame our work, we consider the importance communication including language and framing amongst
78 stakeholders, and provide an overview of shale gas exploration and development and induced seismicity
79 with a particular focus on the UK as a case study. We then present our research in two parts: in Section 2
80 we examine how the risk of induced seismicity is described in expert-led technical reports and in public
81 perception studies of hydraulic fracturing. In Section 3 we present our survey approach and results to
82 investigate perceived risk of seismicity induced by hydraulic fracturing for shale gas, and explore how
83 understanding of perceived risk is complicated by language ambiguity around seismicity¹. We discuss our
84 findings and their implications in in Section 4.

¹ We use the term seismicity in the body of this paper as a catchall term to describe the phenomena of rapidly radiated seismic energy that has been described by terms that include: earthquakes, tremors, and so on. Secondly, although we focus on seismicity in this paper, in doing so we do not

85 Our findings are applicable to a range of geological applications which could induced seismicity (including
86 hydropower dam construction, carbon capture and storage, geothermal energy extraction, energy storage
87 etc.), many of which are considered fundamental to delivering a sustainable future (Trutnevyte &
88 Ejderyan, 2018; Stephenson et al., 2019). Further, the learnings around language, communication, and
89 understanding perceived risk are applicable to issues beyond geological engineering, and are key for
90 supporting stakeholder dialogue for shared decision-making.

91 *1.1 Language and communication in the geosciences*

92 There have been growing moves to increase public involvement in scientific issues - from funding priorities
93 and data collection, to policy decisions - particularly on topics with social and environmental importance
94 such as climate change, flooding, energy policy, and genetically modified crops (e.g. Rowe et al., 2005;
95 Parkins and Mitchell, 2005; Horlick-Jones et al., 2007; Nisbet, 2009). This progression brings a new
96 communication challenge: for scientists, policy makers and the publics to be able to share information,
97 concepts and ideas, and to make shared decisions, they must be able to understand each other. The truth
98 is that within languages there are sub-sections that are only accessible to those with technical expertise
99 on the matter at hand. Specific language frameworks and jargon are prevalent within specific disciplines
100 and underpin the explanation of concepts between experts (Montgomery, 1989; Collins, 2011). However,
101 such language can be incomprehensible to those outside the subject area (Leggett and Finlay, 2001;
102 Sharon and Baram-Tsabari, 2014). This creates an 'unequal communicative relationship' whereby lay
103 publics struggle to comprehend the technical language and goals set by experts (Fischer, 2000, p. 18),
104 particularly as many experts are ill-equipped to communicate with members of the public (Simis et al.,
105 2016).

106 This unequal communicative relationship is likely enhanced in the geosciences where seemingly non-
107 technical, uncertain, or ambiguous terms are used routinely but assume tacit understanding. As an
108 example, geoscientists may refer to *dip* and *strike* of *faults*, *joints*, or *cleavage*, which have specific
109 meanings in geology, but have other meanings in the English language. But tacit understanding is not
110 reliable; loose use of language, ambiguity and poorly defined technical terms can lead to
111 misunderstanding even amongst experts (van Loon, 2000; Doust, 2010) and between sub-disciplines
112 (Collins, 2011).

113 It is well established that how individuals perceive new information is influenced by factors such as
114 expertise, context, prior knowledge, and the language used (McMahon et al., 2015; Venhuizen et al.,
115 2019). Values and motivation, including affiliations and 'world view', have particular influence on
116 perceptions of risk and the assessment of any new information (NASEM, 2017; Roberts & Lightbody,
117 2020), as well as how the information is framed (Pigeon, 2020). Consider the original work on framing by
118 Tversky and Kahneman (1981). In their example, when disease treatment options were framed positively
119 (lives saved) rather than negatively (lives lost) people chose more risky treatment options. Similar work
120 has found that how geoscience data and information is framed affects decision-making (Taylor et al., 1997;
121 Barclay et al., 2011; Alcalde et al., 2017).

122 There was a notable shift in the framing of positive and negative arguments around shale gas extraction
123 in the UK. Early arguments adopted local frames, such as concerns about local effects like induced
124 seismicity, traffic, noise. These arguments were replaced by global frames such as concerns about the
125 climate change implications of developing onshore gas resources (Hilson, 2015), or the changing role of
126 natural gas in the energy transition (Partridge et al., 2017). But, as we show in the remainder of this
127 section, induced seismicity kept a high public and political profile in the UK.

construe any specific importance to this or other issues associated with shale gas extraction. We
merely use it as a pertinent example of the importance of language use in scientific communication.

128 1.2 Hydraulic fracturing, induced seismicity, and shale gas development

129 Hydraulic fracturing (often referred to as ‘fracking’) is the process of fracturing rocks at depth by injecting
130 pressurised fluids. The process locally increases the permeability of the rock formation which is useful for
131 a range of applications ranging from improving water extraction (Cobbing & Dochartaigh, 2007), to
132 enhancing deep geothermal energy production (Breed et al., 2013), to enabling the recovery of natural
133 gas trapped in rocks with a low permeability, such as ‘tight gas’ or shale gas (Mair et al., 2012). Hydraulic
134 fracturing also occurs in nature, usually where geological processes cause geofluids to become
135 overpressured enough to overcome the rock strength and cause the rock to fracture (e.g. Engelder &
136 Lacazette, 1990; Fall et al., 2015).

137 For shale gas extraction, hydraulic fracturing is one of several processes that allow the hydrocarbons to
138 be recovered from the low permeability rocks in which they are trapped (King, 2012). A borehole might
139 be hydraulically fractured as part of shale gas exploration or development, where exploration refers to
140 activities to investigate the commercial viability of a potential shale gas resource, and development refers
141 to activities to support commercial production of the resource.

142 As a rock fractures, seismic energy is released (e.g. Tang and Kaiser, 1998) as a seismic event, or seismicity.
143 For shale gas hydraulic fracturing, because the fracturing process is human-made, the seismicity is
144 categorised as ‘human-induced seismicity’ or, simply, ‘induced seismicity’. Many processes induce
145 seismicity, from mining and quarrying, filling and dewatering reservoirs, to disposing of wastewaters by
146 injection into rock formations (Westaway & Younger et al., 2014; Pollyea et al., 2019). However not all
147 seismic events have any detectable effect in terms of being felt at the surface or even recorded (Kendall
148 et al., 2019).

149 There are a number of approaches to quantify, and so report on, the size of a seismic event. The moment
150 magnitude (M_w) relates to the seismic moment, which is the energy released by the event. The local
151 magnitude (M_L) measures the ground displacement. The two scales M_L and M_w are fundamentally
152 different, and so the M_w and M_L of a seismic event can diverge, particularly for large ($> M 6.0$) and small
153 ($< M 2.0$) events (Clarke et al., 2019; Kendall et al., 2019). Seismologists prefer M_w because it relates to
154 the properties of the fracture (the seismic moment) and because M_L breaks down for events below $M_L 2.0$
155 (Kendall et al., 2019). However M_L is easier to use for real-time reporting, and so is used to report seismic
156 events and to regulate induced seismicity (Butcher et al., 2017). A variety of terms are used by both
157 experts and laypeople to describe a seismic event, including earthquakes, tremors, micro-earthquakes.
158 Seismologists have proposed particular terminology based on the property of a seismic event, such as the
159 frequency content or the magnitude (for example, see Bonhoff et al., 2009; Eaton et al., 2016), but there
160 is no common classification framework. This poses questions such as ‘How big is a small earthquake?’
161 (Kendall et al., 2019).

162 Hydraulic fracturing will be accompanied by release of seismic energy as the rock is fractured by the fluid
163 pressure (Kendall et al, 2019). The energy released by an individual fracture is small, typically representing
164 $M_L -1.5$ (Mair et al., 2012), but if hydraulic fracturing fluids reach a pre-stressed fault larger events can
165 occur (Clarke et al., 2019). Induced seismicity is thus inherent in hydraulic fracturing. But there are
166 uncertainties regarding the measurement, forecasting of and magnitude of these events (Kendall et al.,
167 2019). The nominal detection level for the UK seismic monitoring network (seismograph stations operated
168 by the British Geological Survey) is $M_L = 2.0$ (i.e. events above $M_L 2$ might be measured at the surface)
169 (Kendall et al., 2019), or $M_L 2.5$ in urban areas due to background noise. Acoustic monitoring systems
170 away from background noise such as in mines can record very small seismic events down to magnitude
171 $M_w -4$ (Kwiatek et al., 2011; Jalali et al., 2018). Whether or not an event is felt at the surface depends on
172 several factors, including the seismic moment, the hypocentral depth and the attenuating properties, the
173 structure of the rocks through which the energy travels, and other local conditions such as the stiffness of
174 the ground, the background noise and the time of day (Butcher et al., 2017; Kendall et al., 2019). Further,

175 recorded M_L is dependent on the seismic detection network, including the array density and location
176 distance between source and detector (Butcher et al., 2017).

177 Incidences of felt seismicity associated with hydraulic fracturing for shale gas in the UK, US, Canada and
178 China are well documented (Warpinski et al., 2012; Verdon and Bommer, 2020; Schultz et al., 2020) but
179 when shale gas exploration began in the UK circa 2009, this was not the case. Despite many thousands of
180 hydraulic fracturing treatments, there were no recorded incidences of felt seismicity associated with
181 fracking in the shale gas basins first developed in the USA (Verdon and Bommer, 2020). Seismic events
182 that had been felt were due to geological disposal of hydraulic fracturing waste water rather than the
183 fracking process itself (e.g. Elsworth et al., 2015). However, in 2011 a series of seismic events with
184 maximum magnitude (M_L) 2.3 (Clarke et al., 2014) occurred at the Preese Hall shale gas exploration site
185 in Lancashire (NW England, UK), suspending operations. These seismic events led shale gas activities to
186 have a high public and political profile (Green et al., 2012; Selley, 2012; Clarke et al., 2014), receiving
187 widespread media coverage and stimulating a wave of public protests against shale gas activities (Jaspal
188 & Nerlich, 2014). The UK government introduced a moratorium on hydraulic fracturing for 6 months
189 following the 2011 events. In December 2012 the UK Government lifted the moratorium in England and
190 Wales, but in Scotland moratoria have been applied by Scottish Government. The UK government
191 introduced new regulatory requirements intended to effectively mitigate seismic risks (DECC, 2013a; DECC
192 2013b), including a traffic light system (Figure 1) based on the local magnitude (M_L) of induced events. In
193 November 2019 the moratorium was reapplied following publication of the Oil and Gas Authority's report
194 (BEIS, 2019a; OGA, 2019) on a series of seismic events of up to 2.9 M_L that occurred at the Preston New
195 Road shale gas site, also in Lancashire, in August 2019. Since the 2011 events at Preese Hall, many more
196 incidences of felt seismicity related to hydraulic fracturing have been documented (Schultz et al., 2020;
197 Verdon and Bommer, 2020). It's now understood that the occurrence of felt seismicity from hydraulic
198 fracturing is highly site-specific, and depends on geological and geomechanical conditions of the reservoir
199 and the hydraulic fracturing operation design (Schultz et al., 2020; Verdon and Bommer, 2020), as well as
200 characteristics of the local site (Butcher et al., 2017).

201 It is with this backdrop that we examine the available evidence of expert and non-expert perspectives on
202 the risk of hydraulic fracturing induced seismicity, and the terminology used to describe these risks.

203

204

205 **Figure 1:** The UK's traffic light system for regulating induced seismicity from hydraulic fracturing activities for shale
206 gas extraction, figure from DECC (2013b), made by the Oil and Gas Authority. The traffic light system is based on a

207 risk mitigation technique originally developed for geothermal energy production (Cremonese et al., 2015). It requires
208 operators to monitor seismic activity in real time and if seismic events are detected, to proceed or stop depending
209 on the magnitude (M_L) of these events. Under this regulation, activities at Preston New Road were suspended several
210 times during hydraulic fracturing in December 2018 (OGA, 2019).

211 **2. Induced seismicity and hydraulic fracturing: a review of perspectives and language used**

212 In order to investigate expert and non-expert views and language preferences around induced seismicity
213 and hydraulic fracturing in the UK, we must first define what is meant by 'expert' and 'non-expert' in this
214 context. 'Expert' is a flexible term, but is usually applied to a person considered to be particularly
215 knowledgeable or skilled in a certain field (Lightbody and Roberts, 2019). Here, we consider expertise to
216 refer to in-depth knowledge about an aspect of the hydrocarbon industry, be it technical (environmental
217 regulation, oil field services including geoscience and petroleum engineering) or topical (energy policy and
218 politics, energy or gas markets, regulation, environmental impact assessment, financing projects and
219 investments). The wider publics or 'lay' audiences are not expected to have in-depth technical or topical
220 expertise, and so we refer to them as 'non-expert' or 'lay' audiences in this paper. However, we
221 understand that such categorisations are simplistic; the publics can hold valuable experiential and
222 contextual knowledge, rather than (but not excluding) technical or topical knowledge.

223 To examine expert and non-expert perspectives on induced seismicity we review publicly available
224 resources published before November 2019. For expert views, we look to reports from expert groups such
225 as learned societies, expert panels and scientific enquiries. These reports draw on a range of sources,
226 including peer-reviewed publications in scientific journals, and so represent the state of expert knowledge
227 that is articulated for non-expert audiences, including the publics. We do not consider peer-reviewed
228 publications in scientific journals; the outcomes of such studies will be captured within the expert reports,
229 and peer reviewed publications are not intended for public readership. For lay perspectives, we examine
230 social science studies examining public opinions on hydraulic fracturing, looking for evidence of public
231 views on induced seismicity in particular.

232 We restrict our study to the risk of induced seismicity from hydraulic fracturing reported by expert and
233 lay audiences and the associated language used. We do not seek to determine whether the risk is
234 considered to be acceptable and to whom, and the variables that influence this.

235 A summary of the conclusions on the risk of shale gas induced seismicity from expert-led publications are
236 shown in Table 1A, and from studies of public perceptions around shale gas topics in Table 2. It should be
237 noted that in the review period (2012 to 2019) the state of knowledge about hydraulic fracturing induced
238 seismicity was evolving, as outlined in Section 1.2.

239 *2.1 Expert and lay perspectives on the risk of induced seismicity for hydraulic fracturing*

240 All expert reports that we reviewed, and which examined seismicity risk, concluded that the risks of
241 induced seismicity from hydraulic fracturing in the UK are very low, and that any induced events will be
242 below the threshold of felt seismicity (Table 1). It is therefore fair to surmise that there is general
243 agreement amongst expert bodies that the risks of hydraulic fracturing induced seismicity are lower or no
244 different to other causes of human-made seismicity. To be clear, agreement on low risks associated with
245 induced seismicity does not reflect agreement on or support for other aspects of shale gas exploration
246 and development, such as the business case for, or environmental ethics of, fracking (Howell, 2018; Van
247 de Graaf et al., 2018).

248 All studies of public perceptions (non-expert) around shale gas topics in the UK find that publics associate
249 the risk of induced seismicity with hydraulic fracturing. However, risk of contamination of drinking water
250 is more often of larger concern than induced seismicity. These studies and their findings are summarised
251 in Table 2. Table 2 also illustrates the similarities/differences in the phrases used in these studies to refer

252 to induced seismicity. These differences are typically introduced by researchers either in the research
 253 design or the analysis, rather than in the phrasing used by participants. To examine insights from these
 254 studies in more detail, we first summarise findings from cross-public surveys before we look to the results
 255 of dialogic and deliberative research. In each case, mindful that public views may have been evolving, the
 256 studies are presented chronologically in the order in which they were conducted (not the order in which
 257 they were published). As before, we are interested in the perceived risks of and language around induced
 258 seismicity, and not the public opinion around fracking for shale gas, though the latter is the primary
 259 motivation for many of the studies that we examined.

260 A number of closed-response surveys have been undertaken to assess UK-wide public attitudes towards
 261 shale gas and related topics. The most comprehensive of these in terms of a longitudinal dataset is the
 262 YouGov survey organised by University of Nottingham. The survey was administered 12 times in the
 263 period March 2012 - October 2016 (Andersson-Hudson et al., 2016; O’Hara et al., 2016). Following a
 264 knowledge question which filtered out participants who didn’t know what hydraulic fracturing or shale
 265 gas was, respondents were then asked questions about multiple aspects of shale gas development. One
 266 question asked whether they do or do not associate earthquakes with shale gas, with the option to answer
 267 ‘don’t know’. In the period 2012-2014, there is a steady decline in the number of participants who
 268 associate shale gas extraction with earthquakes and a corresponding increase in those that do not (Figure
 269 2). In the three surveys conducted in 2014 the responses appear to have stabilised.

“Do you associate earthquakes with shale gas?”

270
 271 **Figure 2:** Responses to the ten University of Nottingham surveys administered between 2012-14 via YouGov to
 272 assess public perspectives on shale gas development (O’Hara et al., 2016). During the period 2012-14 the number of
 273 participants that associate shale gas with earthquakes decreases, while the number of participants that do not
 274 associate, or don’t know, increases. Results from the additional two surveys administered between 2014-16 are not
 275 publicly available.

276
 277 The Energy and Climate Change Public Attitudes Tracker is a quarterly UK-wide survey conducted by the
 278 Department of Business, Energy and Industrial Strategy (BEIS, previously the Department of Energy and
 279 Climate Change, DECC), to capture changing public attitudes towards energy and climate change issues.
 280 Questions about shale gas were included in the survey from June 2012, and since 2015 reasons for
 281 support, opposition, or no view have been enquired about (Howell, 2018). One of the reasons for
 282 opposition to shale gas that is consistent across the BEIS surveys is ‘risk of earthquakes’, ranked fourth
 283 out of five common concerns (Bradshaw & Waite, 2017). Opinium Research led two online surveys to
 284 explore public attitudes to fracking in 2014 and 2015 (reported in Howell, 2018). The survey did not ask

285 participants about perceived risks. However, questions from the Opinium Research were adapted for a
286 different online omnibus survey fielded by YouGov, also 2015 (Howell, 2018). Howell (2018) found the
287 majority (43.2%) of respondents who answered a knowledge question about shale gas correctly agreed
288 that “fracking could cause earthquakes and tremors”, whereas 18.8% disagreed (the remainder answered
289 ‘don’t know’). However, the level of positive response for earthquakes and tremors ranked towards the
290 lowest of the range of negative environmental and social risks (including damage to the local environment,
291 water contamination, negative affect on climate change, and health risks). A one-off online survey in 2014
292 (Whitmarsh et al., 2015) finds that 40.4% of participants agreed that they are “concerned about the risks
293 of earthquakes from shale gas fracking”, with 20.8% reporting that they disagreed, and the remainder
294 undecided. In this survey public were marginally less concerned about earthquakes than they were about
295 water contamination.

296 The most recently published survey, UK National Survey of Public Attitudes Towards Shale Gas, conducted
297 in April 2019, is the first to seek to understand what the public knows or thinks about specific regulations
298 for shale gas, including the ‘traffic light system’ for monitoring and regulating induced seismicity (Evensen
299 et al., 2019). The majority of participants felt that the traffic light guidance is not stringent enough, and
300 would oppose any changes to raise the threshold to 1.5 ML, suggesting that concerns around risks of
301 induced seismicity from hydraulic fracturing remain (Evensen et al., 2019).

302 Overall, these surveys indicate that seismicity induced by hydraulic fracturing is an important issue for
303 publics. However, as is the nature of surveys, to some degree the topics of concern are pre-identified
304 during the survey design, and are shaped by the phrasing question (a problem that is well-documented in
305 research methods and risk research: see, for example, Gaskell et al., 2017). For example, the Whitmarsh
306 et al. (2015) survey asked questions in the style “I am concerned about [environmental risk]”; other
307 questions in the same survey were focused on risks around energy security or energy prices, and did not
308 use the words ‘concern’ or ‘risk’, both of which have negative associations. Similarly, Howell (2018) found
309 the question, “fracking could cause earthquakes and tremors”, is interpreted to be a negative statement
310 about fracking, rather than, say, a factual statement. Further, we note that statements regarding
311 earthquake risk were conditional (‘could cause’), whereas all other provided risks except for water
312 contamination were unconditional (‘will cause’).

313 Two studies adopted open survey questions. Craig et al. (2019) studied public views towards fracking and
314 how these changed with distance from a region of County Fermanagh with potential shale gas resources
315 and a granted petroleum exploration license. Survey results, which were gathered in 2014, indicated that
316 risk of ‘increased seismicity’ ranked eighth amongst the ten risks considered to be a concern by survey
317 respondents. All of the identified risks increased with proximity of residence to the licensing area,
318 including the perceived risk of increased seismicity due to hydraulic fracturing. McNally et al. (2018) found
319 seismicity ranked third out of four common disadvantages identified from an open question about
320 advantages and disadvantages of fracking. When the same question was asked about ‘using hydraulic
321 pressure to extract natural gas’, seismicity was not raised as a disadvantage.

322 Analysis of qualitative data presented in the public inquiry on planning permission for shale gas
323 development in Lancashire (held in 2016) found that “*seismic activity was raised regularly in the public
324 sessions. Several of those who spoke had first-hand experience of seismic activity having felt the tremors
325 from Cuadrilla’s hydraulic fracturing at Preese Hall in 2011*” (Bradshaw & Waite, 2017).

326 Williams et al. (2017) reports on deliberative focus group discussions on shale gas development. The
327 groups were held in Northern England in 2013, and Williams et al., reported that explicit concern about
328 induced seismicity was not expressed, although some groups did express ‘worst case scenario’ thinking
329 around a number of potential risk and impact pathways (Williams et al., 2017). Similarly, a series of 1-day
330 deliberations in the UK and the US held in 2014 found that participants did not express particular concern
331 about induced seismicity (Thomas et al., 2017a). In deliberative interviews held in Wales in 2013/14 the
332 risk of earthquakes or tremors was ranked 13th out of 19 pre-identified risks in a card sorting exercise

333 (Whitmarsh et al., 2014). In 2016 a Citizens' Jury (a format for public deliberation) was held in Preston,
334 Lancashire (NW England) approximately 10 miles from the Preese Hall shale gas development.
335 Transcriptions from the proceedings show that while participants raise questions around earthquake risks
336 from shale gas extraction (and geological CO₂ storage), concerns about induced seismicity are not
337 reported to be a dominant issue (Bryant, 2016).

338 2.2 Language used by expert and lay audiences on the risk of induced seismicity

339 As Jaspal and Nerlich (2014) reflect, terms such as 'earthquakes' evoke imagery of destruction and
340 disaster, whereas phrases like 'seismic activity' or 'tremors' are less threatening. Since language is not a
341 neutral tool, the choice of words used by experts, social researchers and public participants might be
342 carefully chosen to communicate particular meaning.

343 Experts use a range of terms to describe induced seismicity (Table 1). The seismic events themselves might
344 be referred to as *micro-seismic events*, *seismicity*, and *earthquakes*. A distinction is made between *natural*
345 and *induced* earthquakes, and the events that may occur from hydraulic fracturing or other human-caused
346 activities are described as being *induced* by or *triggered* by these activities where induced can mean solely
347 due to fracking, and triggered can mean that the occurrence was accelerated by fracking, but might have
348 occurred naturally. The authors use qualifiers such as *minor*, *low*, *small* to indicate the magnitude of
349 seismicity associated with fracking. Finally, while the consequences of seismicity are sometimes referred
350 to in terms of *vibrations* or *tremors*, more often there is a distinction between *felt* and *not felt* events.

351 In some cases, the language around seismicity in policy reports is inconsistent and confusing. For example,
352 a DECC (2013) report lays out regulatory requirements designed "to ensure that seismic risks are
353 effectively mitigated" (p6) and "to prevent any more earthquakes being triggered by fracking" (p19). But
354 the regulations allowed induced seismic events of magnitude (M_L) < 0.5 ("green light"), implying that these
355 events are not considered to be earthquakes, although no definition of the term is provided. On the next
356 page (p20) an additional qualifier is added which gets around this contradiction: the regulations are
357 "designed to prevent any more *perceptible* earthquakes being triggered by fracturing". The 2019 OGA
358 report (which summarised a series of studies commissioned by the OGA to understand and learn from the
359 induced seismicity observed at the Preston New Road development in 2018) concluded that rules based
360 on current understanding of induced seismicity cannot be "reliably applied to eliminate or mitigate
361 induced seismicity" (OGA, 2019). The authors of this OGA report do not define what is meant by induced
362 seismicity (i.e. what magnitude won't be reliably mitigated). As outlined in Section 2.1, it is not possible
363 to eliminate risks of all magnitudes of induced seismicity from the hydraulic fracturing process.

364 In comparison, the terminology to describe induced seismicity reported in public perception studies is
365 much less varied (Table 2). However in many cases, the phrases are selected by the researchers, either
366 when designing the survey question or when reporting on the research outcomes. For example, four of
367 the five closed question surveys about induced seismicity refer to risk of '*earthquakes*'. The researchers
368 designing closed-question surveys might have opted to use the term 'earthquake' since it is commonplace
369 and widely understood, whereas 'seismic activity' might be considered to be jargon. Results from the only
370 survey to add a size-qualifier, asking about '*earthquakes or tremors*' (Howell, 2018), are very similar to the
371 results of surveys which simply asked about '*earthquakes*'.

372 In contrast, of the phrasing chosen by researchers to communicate outcomes from qualitative methods,
373 only one study refers to '*earthquakes*' (Thomas et al., 2017a). Instead, researchers reporting qualitative
374 methods use terms such as '*seismic activity*', '*seismicity*', or '*minor earthquakes*'. These terms might have
375 been selected to reflect the level of risk perceived by participants. The phrases that publics themselves
376 adopted are not reported in these studies, except for in the report on the citizens' jury on fracking where,
377 in their questions, participants wanted to get to grips with whether the 2011 Preese Hall seismic events
378 had been "*real/genuine*" (i.e. caused by hydraulic fracturing) or "*natural tremor*" (i.e. background
379 seismicity) (Bryant et al., 2016, pp 14).

380 While dialogic or deliberative studies in the UK find that risks of induced seismicity tend not to take
381 precedence in the public discussions, that's not to say that the risks are acceptable. Thomas et al. (2017a)
382 report that deliberative groups in the UK and the US felt that if shale gas development were to cause
383 earthquakes, however small, development should not be pursued. Similarly, Williams et al. (2017) reports
384 how one deliberative group reflected that public tolerances to industrial activities which induce seismicity
385 may have changed such that activities that were acceptable in the past are no longer acceptable to the
386 public. Finally, early results from a recent investigation into public attitudes to the UK government's traffic
387 light system to regulate induced seismicity suggest that participants support stringent monitoring of
388 induced seismicity (Evensen et al., 2019). These insights imply that the public's risk tolerance to induced
389 seismicity from shale gas production is low.

390 *2.3 Knowledge, language and risks of induced seismicity*

391 The physical process of hydraulic fracturing will, by definition, release seismic energy – whether the
392 release of this energy is detectable as an 'event' or not. Accordingly, the expert reports that we reviewed
393 conclude that there is risk of induced seismicity from hydraulic fracturing, albeit low. Depending on how
394 'earthquake' is defined (e.g. 'How big is a small earthquake?' Kendall et al., 2019), it could be argued that
395 assertions used to gage public views such as "shale gas development is associated with earthquakes" are
396 factual. Might the questions indicate level of knowledge of the association, rather than indicate the level
397 of perceived risk? Howell (2018) finds that respondents who correctly answer a knowledge question about
398 shale gas are more likely to agree with the statement "fracking could cause earthquakes and tremors"
399 (43.2%) than to answer don't know (38.0%) or to disagree (18.8%). Further, Andersson-Hudson et al.
400 (2019) find that publics more knowledgeable about shale gas have more unified views. Indeed, all cross-
401 public surveys studied here find motivations determine public responses: associating fracking with
402 earthquakes negatively correlates with support for the technology and relate to demographic variables
403 including political views and gender (Andersson-Hudson et al., 2016; 2019; Howell, 2018; O'Hara et al.,
404 2016; Evensen et al., 2017). These findings align with similar studies in Europe (Lis et al., 2015; Evensen et
405 al., 2018), US (Boudet et al., 2014; Graham et al., 2015) and Canada (Thomas et al., 2017b).

406 In summary, through our review and analysis of previous surveys, reports and papers, we have revealed
407 uncertainties in the perceived risk of seismicity induced by hydraulic fracturing for shale gas. There is
408 broad agreement amongst experts that while induced seismicity is associated with hydraulic fracturing,
409 the likelihood of *felt* seismicity is dependent on context-specific technical factors. All the expert reviews
410 concluded that the risk presented by such seismicity is low. Generally these reports distinguish between
411 felt and not felt seismic events, but there is no systematic use of terminology to describe seismicity, nor
412 the risk it presents. We find that associations between induced seismicity and shale gas are common
413 across nearly all public studies that we reviewed. Perceived risk is not ubiquitous amongst all publics, and
414 often other reported environment or social risks take prevalence. However, the level of perceived risk of
415 induced seismicity and understanding around the topic is difficult to compare due to differences in
416 research approaches and the language used to elicit and report on public views. Given the ambiguities in
417 terminology around hydraulic fracturing induced seismicity, it is interesting to consider whether questions
418 around 'risk of earthquakes' might be understood or interpreted differently according to, say,
419 participants' views about shale gas, or understanding of the hydraulic fracturing process. And are
420 ambiguous terms such as 'earthquake' or 'tremor' potentially loaded or leading?

421 In the next section, we explore whether or not knowledge levels affect whether seismicity is associated
422 with shale gas, and how the language used in the questions asked affects the answer provided.

Year	Report (<i>purpose</i>)	Conclusion on (risk of) induced seismicity	Terminology used to describe seismicity
2012	<p>Mair et al. (2012) Royal Society and Royal Academy of Engineering (2012) 'Shale gas extraction in the UK: a review of hydraulic fracturing' <i>Report commissioned by UK Government Chief Scientific Adviser.</i></p>	<p>"Seismic events induced by hydraulic fracturing ... do not produce ground shaking that will damage buildings. The number of people who feel small seismic events is dependent on the background noise." (pp 16)</p> <p>"Magnitude 3 ML may be a realistic upper limit for seismicity induced by hydraulic fracturing (Green et al., 2012)" (pp 41).</p> <p>The report recommends a Traffic Light System to be put in place (transferred learning from geothermal energy developments)</p>	<p>Varied terminology, including: <i>induced seismicity, seismic event, vibrations, felt/not felt, magnitude and intensity.</i></p>
	<p>AEA (2012) AEA Report for European Commission DG Environment 'Identification of Potential Risks for the Environment and Human Health arising from Hydrocarbons Operations involving Hydraulic Fracturing in Europe' <i>Report commissioned by the European Commission DG Environment to inform policy.</i></p>	<p>The risk of "significant" induced seismic activity was considered to be low; the frequency of significant seismic events is judged to be "rare" and the potential significance of this impact is "slight" (pp 60)</p>	<p>Tend only to refer to <i>very small magnitude, seismic activity, earth tremors.</i></p>
	<p>Green, C. A., et al. (2012) Preese Hall shale gas fracturing review and recommendations for induced seismic mitigation. <i>Report commissioned by DECC to examine the possible causes of seismicity at Preese Hall in April/May 2011.</i></p>	<p>The report concludes that the observed seismicity in April and May 2011 was induced by the hydraulic fracture treatments at Preese Hall. The authors also conclude that the risk of induced seismicity should not prevent further hydraulic fracture operations in this area provided that proposed best practice operational guidelines are implemented and followed.</p>	<p>The authors primarily refer to <i>earthquakes or seismic events</i>, and sometimes refer to "<i>small</i>" events/earthquakes.</p>
	<p>Kavalov & Pelletier (2012) European Commission Joint Research Centre (2012) 'Shale Gas for Europe - Main Environmental and Social Considerations' <i>Undertaken by the European Commission's in-house science service to provide evidence-based scientific support to the European policy-making process.</i></p>	<p>"Drilling and hydraulic fracturing activities may lead to low-magnitude earthquakes" (pp 26).</p> <p>The authors make no conclusions on risk, but recommend that "the severity and probability of this hazard should be carefully assessed on site by site basis".</p>	<p>Refer only to <i>low-magnitude earthquakes</i></p>
2013	<p>DECC (2013c) DECC Report 'About shale gas and hydraulic fracturing' <i>Government response to common questions raised in the UK-wide consultation on shale gas and fracking.</i></p>	<p>Regulations are designed to "ensure that seismic risks are effectively mitigated".</p>	<p>A mix of terms are used, including <i>seismicity, events, activity, tremors</i>. The most frequent term is <i>earthquake</i>, in some cases with qualifiers such as <i>perceptible, large, small, very small</i>.</p>

	<p>National Research Council (2013) US National Research Council 'Induced Seismicity Potential in Energy Technologies'</p>	<p>"The process of hydraulic fracturing a well as presently implemented for shale gas recovery does not pose a high risk for inducing felt seismic events" (pp 18).</p>	<p>Only refer to <i>earthquakes</i> and <i>seismicity</i></p>
	<p>Cook et al. (2013) Australian Council of Learned Academies (ACOLA) Unconventional Gas Production: A study of shale gas in Australia <i>Report the Prime Minister's Science, Engineering and Innovation Council</i></p>	<p>Induced seismicity from hydraulic fracturing itself does not pose a high safety risk (pp 137). Risks can be managed by adopting a range of mitigation steps.</p>	<p><i>Earthquakes</i> or <i>seismicity</i> are used most often, but with qualifiers such as <i>minor</i>, <i>low magnitude</i>, <i>felt</i>.</p>
2014	<p>European Commission (2014) European Commission Recommendation on minimum principles for the exploration and production of hydrocarbons using high-volume hydraulic fracturing <i>EU Regulation/Legislation</i></p>	<p>The recommendations refer only to risk assessment protocols for induced seismicity, not the risk of seismicity.</p>	<p>Refers only to <i>seismicity</i></p>
	<p>Scottish Government (2014) Expert Scientific Panel on Unconventional Oil and Gas Development <i>Report from an expert panel set up by Scottish Government</i></p>	<p>"seismic effects are expected to be small in magnitude" (pp 39); "very low likelihood of felt seismicity" from fracking (pp 48)</p>	<p>A number of phrases are used. <i>Seismicity</i> is often pre- by <i>micro-</i>, <i>trigger/induce</i>, or <i>felt</i>. Also refer to <i>tremors</i>, (<i>natural</i>) <i>earthquake</i>.</p>
2015	<p>TFSG (2015) Task Force on Shale Gas 'Assessing the Impact of Shale Gas on the Local Environment and Health' <i>Second report by the industry-funded expert panel Task Force on Shale Gas.</i></p>	<p>"Shale gas operations have the potential to cause tremors albeit not at a level higher than ...other comparable industries in the UK, nor at a frequency or magnitude significantly higher than natural UK earthquakes" (pp 9).</p>	<p>Refer mostly to <i>earthquakes</i> and <i>tremors</i> (and to a lesser extent, '<i>events</i>'), but often prefacing these terms with words such as <i>small</i>, <i>tiny</i>, <i>minor</i>, <i>micro</i>.</p>
	<p>Cremonese et al. (2015) Institute for Advanced Sustainability Studies (IASS) Potsdam Policy Brief Shale Gas and Fracking in Europe <i>Policy brief to inform European Policy</i></p>	<p>"The rock fracturing process generates small seismic events of a very low magnitude (microseismicity), which are not generally felt by humans." Site specific stress investigations will significantly lower risk of triggering major events. (pp 3).</p>	<p>Refer to <i>small</i> induced <i>seismic events</i>, and <i>microseismicity</i>.</p>
2016	<p>Baptie et al. (2016) Unconventional Oil and Gas Development: Understanding and Monitoring Induced Seismic Activity. <i>Report commissioned by Scottish Government</i></p>	<p>Hydraulic fracturing to recover hydrocarbons is generally accompanied by earthquakes with magnitudes of less than 2 ML that are too small to be felt. (pp 2).</p>	<p>Only refer to <i>earthquakes</i> and <i>seismicity</i> or <i>seismic activity</i>, but often specify that these events are induced. Sometimes refer to <i>felt</i>.</p>
2018	<p>Scottish Government (2018) Report for Scottish Government's SEA on unconventional gas <i>Report commissioned by Scottish Government</i></p>	<p>The risk of fracking-induced felt seismicity causing damage to properties or people at the surface is considered to be very low (para 13.9). Risk table (14.1) reports that felt seismic activity would have minor negative or negligible effect on activities.</p>	<p>Range of terms including <i>felt seismicity</i>, <i>earthquakes</i>, <i>trigger</i>.</p>
	<p>Delebarre et al. (2018) House of Lords Briefing paper CBP 6073 'Shale gas and fracking'</p>	<p>No position indicated - but quote several expert reports that state the risk of induced seismicity can be managed.</p>	<p><i>Seismicity</i> is used most frequently. <i>Earthquakes</i> and <i>events</i> also commonly used. <i>Tremor</i> and <i>trigger</i> used infrequently.</p>

	<i>Briefing paper to inform House of Lords debate.</i>		
2019	BEIS (2019b) Guidance on fracking: developing shale gas in the UK (updated 12 March 2019) <i>UK Govt Department for Business, Energy, and Industrial Strategy</i>	"Measures are in place to mitigate seismic activity." (Section 1, par 4)	<i>Seismicity or seismic activity</i> are most often referred to. Do not refer to <i>earthquakes</i> .
	OGA (2019) Oil and Gas Authority 'Interim report of the scientific analysis of data gathered from Cuadrilla's operations at Preston New Road' <i>Summary outcomes from four reports commissioned by OGA in response to induced seismicity at Preston New Road.</i>	It is currently not possible to "reliably eliminate or mitigate induced seismicity" (pp 13).	<i>Seismicity</i> is most often used, with some reference to <i>events</i> and <i>activity</i> .

424 **Table 1:** A compilation of publicly available expert reports on hydraulic fracturing for shale gas which address
425 induced seismicity, the key conclusion regarding risks of induced seismicity and the phrasing used in the reports to
426 refer to seismicity. While we primarily examine policy-facing reports from the UK, we include examples from EU
427 policy, Australia and the US.
428

	Source	Year data collected; method/approach; sample size	Findings on public perception of induced seismicity	Phrases adopted (by who)
Surveys	Andersson-Hudson et al. (2016)	2014 (University of Nottingham YouGov survey, closed questions; sample size: 3,822)	Whether or not <i>earthquakes</i> are associated with hydraulic fracturing is an indicator of opposition or support for shale gas.	Earthquake (researcher's phrasing in the closed survey question)
	Craig et al. (2019)	2014 (face-to-face surveys in four locations, open questions; total sample size: 120)	Risk of <i>increased seismicity</i> was ranked 8 out of 10 identified risks associated with fracking.	Increased seismic activity (researchers phrasing in their analysis of open question response)
	Evensen (2017)	2014 (University of Nottingham YouGov survey, closed questions; sample size: 3,823 + US survey, sample size: 1,625)	UK public associated <i>earthquakes</i> with shale gas more than US publics.	Earthquake (researcher's phrasing in the closed survey question)
	Whitmarsh et al. (2015)	2014 (local/regional online survey, closed question; sample size: 1,457)	When asked if they were concerned about the risks of <i>earthquakes</i> from shale gas fracking, 40.4% agreed and 20.8% disagreed.	Earthquake (researcher's phrasing in the closed survey question)
	Howell (2018)	2015 (YouGov online omnibus survey, closed question; sample size: 1,745)	Fracking could cause <i>earthquakes and tremors</i> (43.2% agree, 18.8% disagree).	Earthquake or tremor (researcher's phrasing in the closed survey question)

	Andersson-Hudson et al. (2019)	2016 (University of Nottingham YouGov survey, closed question; sample size: 4,992)	Whether or not <i>earthquakes</i> are associated with hydraulic fracturing is an indicator of opposition or support for shale gas.	Earthquake (researcher's phrasing in the closed survey question)
	McNally et al. (2018)	2017 (face-to-face surveys in one location, open and closed questions; sample size: 200)	<i>Seismicity</i> was raised as a common concern when the survey used a "fracking" frame, but was not when survey used a 'hydraulic pressure' frame.	Seismicity (researcher's phrasing in their analysis of open question response).
	Evensen et al. (2019)	2019 (YouGov online survey, closed question; sample size: 2,777)	Some level of concern around the risks of <i>seismic activity</i> is implicit in the public attitudes towards the traffic light system (which is perceived not to be stringent enough).	Seismic activity (researcher's phrasing in the closed survey question)
Deliberative approaches	Whitmarsh et al. (2014)	2013-2014 (deliberative interviews, sorting risk cards; sample size: 30)	Minor earthquakes were ranked 13th out of 19 pre-defined risks.	Minor earthquake (researcher's phrasing in risk cards which interviewees ranked)
	Williams et al. (2017)	2013 (six deliberative focus groups; total sample size: 48)	Explicit concern about induced seismicity wasn't expressed.	Seismicity (researcher's phrasing in their analysis)
	Thomas et al. (2017a)	2014 (series of four 1-day deliberative workshops, two in UK, two in the US; total sample size: 55)	Some concerns were raised regarding earthquake risk, but these weren't particularly important in the context of the deliberations. However, all four groups felt that if shale development were to cause earthquakes, no matter how small, shale gas should not be pursued at all.	Earthquake (researcher's phrasing in their analysis)
	Bradshaw & Waite (2017)	2016 (qualitative analysis of a public enquiry into shale gas in Lancashire, UK; sample size: N/A)	Concerns about seismic activity were voiced by publics during the inquiry proceedings.	Seismic activity (researchers' phrasing in the paper)
	Bryant (2016)	2016 (citizens jury in Lancashire; sample size: 15)	Questions about seismic activity were asked, but concerns about induced seismicity wasn't explicitly mentioned in the deliberation outcomes.	"real" or "genuine" earthquake, "natural tremor", as referred to by participants

429

430 **Table 2:** A compilation of published studies which report on public perceptions of induced seismicity in the UK. These
431 are divided into surveys (many of them UK-wide) and more qualitative approaches such as focus groups, and each
432 group is ordered chronologically in terms of when the data were gathered (not in terms of when the papers were
433 published). We identified whether the phrasing used to describe seismic events was dictated by the language of the
434 survey questions, the researcher undertaking the analyses, or the participants themselves.

435 **3. A survey to examine the rationale and language use behind perspectives on induced seismicity and**
 436 **hydraulic fracturing**

437 **3.1 Methodology**

438 *3.1.1 Data collection*

439 We recruited 387 participants from a series of geoscience events on shale gas that were held in 2014,
 440 including conferences and public talks (see Table 3). We invited attendees to voluntarily complete and
 441 return the surveys, which were anonymous. Our sample includes 204 participants from shale gas specific
 442 conferences, 85 participants from geoscience conferences (that were not shale gas specific), and 98
 443 participants from science outreach events² on shale gas. Since a number of individuals attended several
 444 of the conferences and events we requested that people only complete the survey once.

445

Acronym	Event name (location; date)	Description	N (surveys)
Shale gas specific events			
ESGOS	European Shale Gas and Oil Summit (London; 09/2014)	An industry led conference on shale gas	40
UGA	Unconventional Gas (Aberdeen; 03/2014)	An industry led conference on shale gas	28
SGUK	Shale Gas UK (London; 03/2014)	An industry led conference on shale gas	98
Geoscience events			
TSG	Tectonic Studies Group Annual Conference (Cardiff; 01/2014)	The annual conference of the Geological Society of London specialist group covers a range of topics relevant to tectonic studies. The event included a technical session on hydraulic fracturing and induced seismicity, followed by an open discussion.	57
CCG	Communicating Contested Geoscience (London; 06/2014)	A Geological Society of London conference about issues facing controversial geoscience topics, including shale gas.	66
Public events			
TFA	TechFest (Aberdeen; 09/2014)	Talk and discussion at a local science festival	30
CSA	Café Science (Aberdeen; 02/2014)	Talk and discussion at a Café Science, a popular science communication series organised across the UK.	59
CHL	Coffee House Lectures (Glasgow; 11/2014)	Talk and discussion at a local research communication series	9

446 **Table 3:** The events where attendees were invited to anonymously complete surveys. Public events were generally
 447 small local events.

448 *3.1.2 Survey design*

449 We adapted a subset of questions from the University of Nottingham surveys (O’Hara et al., 2014;
 450 Andersson-Hudson et al., 2016). The questions we used were intended to gather information on the
 451 perceived risks of and level of support for shale gas development, and asked for closed answers to a series

² These events lasted between 1-2 hrs and consisted of an interactive talk (by one or more of the authors of this paper) followed by a discussion session. All three talks were part of small local events held in Scotland.

452 of statements about shale gas. Crucially, in our modified survey, participants were asked to provide
453 reasoning for the answers they gave.

454 Conference participants were asked to report which sector they worked in, and all participants were asked
455 to report their sources of information about or experience of shale gas.

456 Full survey data (raw and analysed) are available, see Data Availability statement.

457 3.1.3 Data Analysis

458 In this work, we consider only the responses to the closed question “*please state whether you do or do*
459 *not associate earthquakes with shale gas*” from which respondent could select either ‘do’, ‘do not’, or
460 ‘don’t know’, and a subsequent open question seeking the reasoning behind the selected answer to the
461 closed question. In total 385 participants completed the closed question (99% of survey respondents),
462 and 292 participants provided informative responses to the open question (67.5% of survey respondents).

463 Closed answers were coded numerically. Open answers were categorised through thematic coding to
464 enable analysis. The codes for thematic analysis were derived iteratively as follows: First, the three
465 authors of this paper worked separately on open coding (i.e. inducing themes from the qualitative answers
466 to all questions). The three authors then had a series of workshops to share identified codes, determine
467 similarities or differences in our codes, and then discuss and reconcile the identified themes, and both the
468 themes and their definition or scope agreed. The authors then worked separately again to apply the codes
469 across all qualitative answers (in several cases a single answer was double or triple coded). The lead author
470 then co-ordinated the codes, seeking consensus in the few cases of disagreement between the applied
471 codes.

472 Thematic analysis of all qualitative data derived a total of 26 themes, of which 15 apply to answers about
473 induced seismicity. These are shown in Table 4. Qualitative answers were coded as null if the content was
474 irrelevant, i.e. did not explain the rationale for the answer provided (the most common example being a
475 knowledge statement about the topic, for example, “I’ve analysed this issue”, “I work on this topic”) or
476 the meaning of the response was ambiguous and couldn’t be deciphered. Overall 80% of respondents
477 provided qualitative responses that were thematically coded.

478 We examine how these themes vary with job sector and knowledge level. Job sector responses were
479 grouped into academia, industry, civil service, and other. Most of the 289 conference participants who
480 completed the survey were from industry (52%) and academia (30%), with only 12% from the civil service
481 (3% did not answer this question). Level of knowledge about shale gas was inferred from a question about
482 the primary sources of information about shale gas, which 95% of survey respondents answered.
483 Responses were grouped into no prior information, information from media reports, expert reports, and
484 academic research. We consider respondents whose information sources include reports and academic
485 papers to be the most knowledgeable. The majority (81%) of the conference attendees were in this
486 knowledge category, with 40% obtaining information from academic papers and 41% from reports. In
487 contrast most (60%) public talk attendees sourced information about shale gas from media.

488 The public cohort were not intended to represent the perspectives of the general public. The surveys were
489 completed at the end of a public talk and discussion on the topic of shale gas, in which induced seismicity
490 was raised, and so these publics are both interested and informed, and therefore cannot be a proxy for
491 UK-wide attitudes and responses. Instead, the public cohort allow us to examine answers for those who
492 obtain the majority of prior information, if any, through media sources (most conference attendees do
493 not fit this category). Public respondents were not asked about employment sector.

494 We compare results from our survey with those from the 10 University of Nottingham YouGov surveys
495 (O’Hara et al., 2016). While the Nottingham YouGov surveys document a broad decline in the number of
496 respondents that associate shale gas with earthquakes (see Figure 2), the results for the three surveys
497 undertaken in 2014, the period in which we undertook our surveys, do not show any decline. We use
498 average values from 2014 surveys (48% do, 27% do not, and 25% don’t know) to represent UK-wide views,
499 against which we compare our results. For simplicity, we refer to these as the ‘*UoN 2014*’ surveys and
500 results.

Code	The reasoning provided to explain the participant's response to the closed question "Do you associate shale gas with earthquakes?" indicates that....	Dir .
Evidence	There is evidence that shale gas extraction [causes/induces/is associated with] earthquakes. <i>Includes references to events in the USA. References to UK events are coded as below.</i>	↑
Blackpool	Any reference to the seismic sequences at Preese Hall in 2011 as evidence of risk of earthquakes. <i>Includes references to Lancashire, Blackpool, Cuadrilla or more broadly to UK events.</i>	↑
Inconclusive	There is currently not enough evidence to (conclusively) say whether or not shale gas extraction [causes/ induces/is associated with] earthquakes. <i>Includes reference to a need for further research/data (to understand the positive and negative impacts, to improve technology and so on)</i>	↔
No evidence	Shale gas extraction is not associated with [does not cause or induce / is associated with] earthquakes.	↓
Knowledge	Respondent doesn't feel that they know enough about shale gas extraction to say. Or they are on the fence.	↔
Media	Reference to the media coverage of shale gas extraction. Phrases include: <i>press, news, high profile, reporting, public concern, miscommunication, scaremongering, hype, anti-fracking activist, anti- lobby.</i>	↑
Fracturing rock	Shale gas extraction requires the reservoir rock to be hydraulically fractured. This process will release seismic energy. Phrases include: <i>inherent/obvious, fracturing rock, high-pressure fluids, stress change, trigger.</i>	↑
Waste-water	Shale gas extraction may not induce earthquakes, but the geological disposal of waste-water (associated with fracking) does. Phrases include: <i>waste water, waste disposal/injection, USA events.</i>	↑
Reactivation	There is a risk that shale gas extraction may cause earthquakes because the process may reactivate existing fractures and faults which could cause seismicity	↑
Magnitude	The magnitude of any seismic events related to fracking will be very small. Phrases include: <i>micro (seismic/earthquake), tremor, low intensity/energy, tiny, cannot feel them, insignificant, low consequence/impact</i>	↓
Low risk	The risk that shale gas extraction [causes/induces/is linked with] earthquakes is very low. Phrases include: <i>is possible, rare, unlikely, low risk, minor, little impact, not a significant risk.</i>	↓
Definition	Comments or questions how earthquake is defined.	↔
Regulation	The risk that shale gas extraction activities may cause earthquakes can be managed by appropriate regulation and monitoring. Includes reference to regulation, appropriate regulation, enforcing regulation, best practice. Phrases include: <i>monitoring, controllable, manageable</i>	↓
Normal	Any seismic activity that may be induced by shale gas extraction is no different to everyday/background/other activities or industries. i.e. not unique to fracking.	↓

Site	Any risk posed by shale gas extraction is location or place specific. Phrases include: <i>determined by the geology of the region, the depth of the resource, the population etc.</i>	↔
-------------	--	---

502 **Table 4:** Codes identified for thematic analysis of participant responses to an open question asking them to provide
503 reasoning for the answer they gave to the closed question “Do you associate shale gas with earthquakes?”. The
504 codes are often directional, i.e. they are used to reason why earthquakes may be associated with shale gas
505 (positive ↑), or why earthquakes may not be associated with shale gas (negative ↓). If the code is not directional
506 it is considered to be neutral (↔).

507 3.2 Survey Results and Analysis

508 3.2.1 Closed question responses

509 In total 55% of survey respondents who answered the closed question “do you associate shale gas with
510 earthquakes” ‘do’ associate shale gas with earthquakes, 37% ‘do not’ and 7% ‘don’t know’ (Figure 3A).
511 Compared to public attitude surveys asking the same question throughout 2014, our survey finds more
512 respondents ‘do’ (+7%) and ‘do not’ (+10%) associate shale gas with earthquakes and far fewer ‘don’t
513 know’ (-18%). Overall our respondents are much more decided than the general public (see Figure 2,
514 O’Hara et al., 2016). Of our cohort, we find more participants from professional conferences and events
515 that are about, or have sessions about, shale gas ‘do’ associate shale gas with earthquakes (58%) than
516 participants attending public talks (48%) (Figure 3B).

517 We observe no systematic trend between the closed answer responses and the level of participant
518 knowledge about shale gas, except that higher the knowledge levels, the fewer ‘don’t know’ responses.
519 Yet there are differences in responses (Figure 3C); those who obtain their information from the media and
520 reports are more likely to answer ‘do’ associate shale gas with earthquakes, a higher proportion of those
521 with no knowledge of the topic ‘do not’, and the most knowledgeable groups have equal proportion of
522 respondents ‘do’ and ‘do not’ associate shale gas with earthquakes. When grouped into experts and non-
523 expert groups (those who source information from research and reports, and those who had no prior
524 information or obtained information from the media, respectively), 56% of experts (n. 276) associate shale
525 gas with earthquakes and 39% do not. These proportions are very similar to non-experts (n. 109) where
526 53% do and 33% do not, and are in fact very similar to the views of UK-wide publics in 2013, see Figure 2.
527 However, grouping in this way masks a difference in responses between those who obtain information
528 from research articles and those who use reports. For the latter, shale gas is predominantly associated
529 with earthquakes, (64% do; 31% do not) whereas for the former, there is a fairly even split (49% do; 47%
530 do not) (Figure 3C). Respondents who source information from research articles are not undecided, their
531 views are apparently polarised.

532 The only group that predominantly do not associate shale gas with earthquakes are those with no prior
533 knowledge of shale gas, although this sample is very small (n. 16). Our results present a more nuanced
534 view than the results of Andersson-Hudson et al. (2016) which find that those with more knowledge about
535 shale gas are more likely not to associate shale gas with earthquakes.

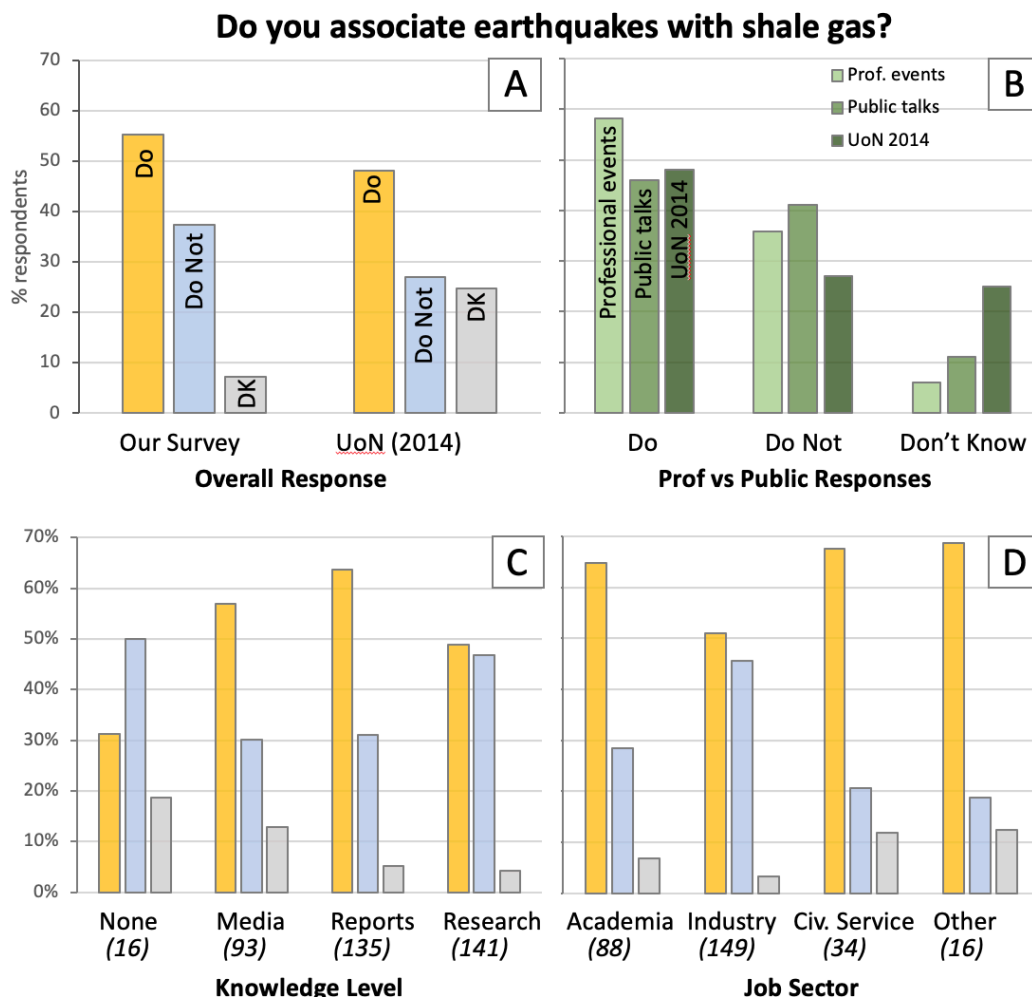

536 It would be fair to presume that most academics would source their information from research papers,
537 and so it is interesting that the results for job sector present quite different results (Figure 3D). Two
538 response profiles emerge from job sector results: the majority of academics and civil service workers (65%
539 and 68% respectively) ‘do’ associate earthquakes with shale gas, and a much smaller proportion ‘do not’
540 (28%, 21%, respectively). In contrast industry respondents present an even mix of views (51% do; 46% do
541 not), similar to those that obtain information from research articles.

542 3.2.2 Open question responses

543 Thematic analysis of the open responses that provided reasoning for participants’ closed answer to the
544 question ‘do you associate shale gas with earthquakes’ identify 15 codes, which are shown in Table 5; a
545 thematic code definition is listed in Table 4. Often multiple codes apply to a given answer, and so in total,
546 there are 443 codes for the 292 qualifying responses. Codes are ranked for frequency in Table 5. The six
547 most frequently used codes are identified over 30 times in participant responses, and these themes are
548 examined in more detail in Table 6.

549 Themes relating to *magnitude* were raised most often, occurring in 40% of participant responses. Indeed,
550 the *magnitude* theme accounted for over a quarter of the total number of codes applied across all open
551 responses (Table 5), inclusive of knowledge level or job sector (Table 6). The code is equally prevalent
552 across reasoning to support ‘do’ and ‘do not’ responses, but less frequent for ‘don’t know’ answers (where
553 unsurprisingly *inconclusive* and *knowledge* themes become important even though the sample is very
554 small).

555 The *magnitude* theme illuminates uncertainty in what is understood to be an earthquake, and raises
 556 questions around terminology. This is best illustrated using example answers from this theme, shown in
 557 Table 7. Participants that ‘do’ or ‘do not’ associate shale gas with earthquakes explain that the
 558 earthquakes will be small. Participants that ‘don’t know’ also refer to the size of the earthquake. There
 559 are examples in the rationale provided for all three closed answer responses that indicate that the
 560 seismicity that they associate with shale gas are not ‘earthquakes’, but are instead ‘tremors’, ‘events’,
 561 ‘microseismic’ or some other term. Thus, we find that respondents provide the same reasoning to support
 562 different closed answers; earthquakes are small, and/or the term earthquake isn’t appropriate. Other
 563 common codes include *low risk* and *media*. Responses coded as *low risk* refer to low risk, low likelihood
 564 or low consequence (Table 7), and the *low risk* rationale is provided to explain closed responses for all
 565 three categories (‘do’, ‘do not’, ‘don’t know’). That is, whether respondents ‘do’, or ‘do not’ associate shale
 566 gas with earthquakes, or they ‘don’t know’, they consider the risk to be ‘insignificant’, ‘minimal’,
 567 ‘unimportant’, ‘very low’ and so on. In contrast, *media* is used mostly to describe reasons for answering
 568 ‘do’, alongside reference to the Blackpool (Preese Hall) seismic events, and the rationale that *fracturing*
 569 *rock* inevitably releases seismic energy and so fracking and earthquakes are associated by definition.
 570 Where the *media* theme is used for ‘do not’ responses, often the respondent is expressing judgement
 571 about the accuracy or veracity of media claims.
 572

573
 574 **Figure 3 (A)** Comparing the results of our surveys with UK-wide results from 2014 (UoN 2014; O’Hara 2015), we
 575 find that while results for ‘do’ associate shale gas with earthquakes (orange) for both surveys are similar our survey
 576 results have more ‘do not’ (blue) and much fewer ‘don’t know’ answers (grey).

577 **(B):** Participants from professional fora (conferences and events, pale green) associate earthquakes with shale gas
578 more than participants from public talks on shale gas (green). Results are compared to UK-wide results from 2014
579 (UoN 2014; O’Hara 2015) (dark green).

580 **(C):** To gauge knowledge levels of our survey participants, we asked respondents to select where they source their
581 information from about shale gas which we used as a proxy for their level of knowledge, with ‘research papers’
582 indicating the greatest knowledge and ‘no previous information’ indicating the least prior knowledge. There is no
583 overall trend to the results, suggesting that answers are not simply determined by knowledge level. In fact, those
584 who obtain information from research present an ~equally polarised response, which is different to information
585 from reports and the media where the dominant answer is that earthquakes are associated with shale gas. The
586 only group to report that shale gas is not associated with earthquakes is the small sample of respondents that
587 obtained no information about shale gas prior to attending the event where they completed the survey.

588 **(D):** The majority (83%) of participants recruited at conferences and events (n. 272) source from industry and
589 academia (public participants were not asked their job sector). We observe some differences in closed question
590 responses between the different sectors; while the majority of participants from academia, the civil service and
591 other sectors predominantly report that earthquakes are associated with shale gas, industry participants are
592 almost 50:50 do and do not associate shale gas with earthquakes. Very few of those from industry and academia
593 (~5%) answer don’t know.

594

595 Two additional themes are identified in the rationale for ‘*do not*’ responses. First, the argument that any
596 earthquakes associated with shale gas extraction will be no more significant than other everyday
597 background seismicity or industry processes, and so is considered to be *normal*. This code is unique in that
598 it is used mostly to support *do not* responses. Further, in their reasoning for ‘*do not*’ responses, a number
599 of participants raise questions about how the term earthquake is *defined*. Themes around earthquake
600 *definition* also arise within rationale for ‘*don’t know*’ responses (Table 7), with the same questions being
601 raised regardless of the answer: ‘*what is the difference between microseismic event and an earthquake?*’.
602 Some respondents confidently assert that microseismic events or tremors are not earthquakes, others
603 indicate that earthquakes refer to ‘natural’ seismic events (similar to comments made by the Citizens Jury
604 participants reported in Bryant, 2016).

605 Results presented in Table 6 indicate that neither knowledge level or job sector have any significant
606 influence on the themes raised in open responses. We observe only two small trends; participants from
607 industry tend to appeal to *media* themes more than other sectors, and academics are more likely to refer
608 to *Blackpool* events (i.e. the Preese Hall events) as an indicator that earthquakes are associated with shale
609 gas development.

610

619

Table 5: The frequency of use of different thematic codes in the reasoning provided for participants' answers, showing total number of times the code was applied and, in brackets, the percentage relative to the number of responses in that category (do, do not, don't know). High frequency codes are coloured pale yellow ($\geq 10\%$) and yellow ($\geq 20\%$). One answer (reasoning) could have more than one code. At the bottom of the table codes are ranked for frequency, and the eight codes that occur over 20 times are coloured in blue. These themes are examined in detail in Table 6.

Table 6: Code frequency and (A) different information sources (for all participants) and (B) employment sector (for conference attendees) for the six most frequent codes (organised from left to right in order of code frequency). Information sources include no source (-); media (M); reports (R); and (A) research (academic) papers. Information about employment sector was asked for conference attendees only and include academia (A); industry (I); civil service (CS); and other (O). The count for each code is normalised to the total count for that code. These values are then colour coded as shown in the key to indicate where codes are used by particular knowledge or employment groups, or to support particular answers.

	Closed response	Example open responses (quotes) provided to explain the participant's answer to the closed question "Do you associate shale gas with earthquakes?"
Magnitude	Do	"the earthquakes associated with shale gas are very small", will be "microseismic earthquakes that won't be felt", "small magnitude events" or "minor tremors".
	Don't know	"major earthquakes probably unlikely", fracking may cause "seismic activity, but not quakes".
	Do not	"there may be possible tremors - not earthquakes", "events will be "mostly unfelt, very small events", or that there a "very few cases [with] little intensity".
Risks	Do	Shale gas "can trigger earthquakes but very rarely", "has the potential to induce seismic activity, but the risk is not a significant" and "any induced seismicity [has] small consequences".
	Don't know	"It is probably unlikely that fracking triggers major earthquakes", there is "probably an association but the risk is relatively trivial" and earthquakes might be associated "with a tiny minority of shale [operations, they are] not an intrinsic by product".
	Do not	"Seismicity risks are minimal and manageable", "insignificant", "very low", "unimportant", and so "don't consider it [to be] a significant hazard".
Media	Do	Earthquakes are associated with shale gas due to "publicity", "media reports" "media portrayal and local campaign group resources". Responses also include judgement statements such as "thanks to the media I associate fracking with [earthquakes], but I don't agree".
	Don't know	"media and other bias form of reporting on shale gas give this impression however I don't know of any evidence of the link".
	Do not	"'Earthquakes' are associated publicly with shale gas thanks to inaccurate media reporting", "while I don't [associate shale gas with earthquakes], from media alone I would do".
Normal	Do	"We have a lot of evidence of earth tremors associated [with shale gas], but these are...comparable to historic mining activity in the UK"
	Do not	"Earthquakes can be induced from many different types of industrial processes", "numerous unfelt earthquakes occur daily, and [there are] only a select few examples of fracking caused felt earthquakes", "any earthquakes from shale gas will be negligible versus natural seismicity".
Definition	Do	"Fracking causes microseismicity, in rare occasions they cause earthquakes. Where is the transition between microseismic [events] and earthquakes?" Fracking does "create microseismicity... not on the scale you would call an earthquake". "Earth tremors or seismic events is more appropriate than earthquake".
	Don't know	Fracking might cause "tremors but not specifically earthquakes". "I think of earthquakes as being of natural origin"
	Do not	"I don't think the minor, largely insensible tremors associated with shale gas merit the term 'earthquake'." "Seismicity" "tremors" "microseismicity" "is not an earthquake".

631 **Table 7:** Example open responses to illustrate how the most common codes are used to defend the range of
632 participant responses to whether or not they associate shale gas with earthquakes. *Magnitude* is generally used to
633 defend do and do not answers, *risks* is used for all responses, whereas *media* most often applies to 'do' answers.
634 *Normal* and *definition* codes tend to be applied to *do not* answers.

635 3.2.3 Language and terminology

636 A theme that is applied in particular to the rationale for 'do not' answers refers to the definitions of
637 earthquakes, indicating that different phrases are more appropriate depending on the scale, size or
638 magnitude of the seismic event. We examine the language used within participants' open responses to
639 determine whether there are any language preferences amongst different answers or different survey
640 groups.

641 Participants used a range of terms to describe or refer to earthquakes. Similar words are used to describe
642 earthquakes in responses for both 'do' and 'do not' closed answers, though there is some indication that
643 words like *seismic* and *tremor* are used more for 'do not' responses. We find that more knowledgeable
644 participants (experts - those that obtain information from reports and peer-review publications) are four
645 times more likely to use phrases such as '*seismicity*' and '*minor*' than less knowledgeable respondents. In
646 terms of job category (conference participants only), academics use the phrase '*earthquake*' far more
647 than those employed in other sectors, and civil service employees prefer '*tremor*' rather than '*micro*' or
648 '*induced*' seismicity, and more often refer to '*energy*' of the event.

649 Finally, an undercurrent theme to all the open responses was to critique the question that they were
650 asked, which was about perceived association between shale gas and earthquakes. As noted in the
651 previous section, many participants raised questions about the phrase '*earthquake*', claiming it was '*too*
652 *strong*', and that any seismicity that might arise from shale gas development would not be '*earthquakes*'
653 but '*tremors*' or '*micro-earthquakes*'. Others preferred to mention earthquake consequences in terms of
654 felt or not-felt, or damage-inducing or not. Several participants critique the use of the phrase '*shale gas*',
655 mentioning that they did not associate *shale gas* with seismicity, but they do associate *the hydraulic*
656 *fracturing technique* (by which shale gas is extracted) with seismicity. Others note that the question is
657 leading. Finally, most of the respondents that raised themes relating to the code *low risk* were essentially
658 communicating that whether they 'do' or 'do not' associate shale gas and earthquakes, it does not concern
659 or worry them (see Table 7). These statements make clear that, for our sample, associating earthquakes
660 with shale gas does not necessarily indicate concern about shale gas induced seismicity.

661 4. Discussion

662 The results from our survey reflect a snapshot of participant views from 2014 about hydraulic fracturing
663 induced seismicity. Further, our results show perspectives from the UK only, a country with low
664 background seismic activity, and for English language use. The results were not intended to inform
665 whether or not people associate earthquakes with shale gas, but, rather, to explore the underlying
666 rationale for the apparent differences in perspectives on the topic, particularly between experts and non-
667 experts. It is important to acknowledge that perspectives of both experts and publics are likely to have
668 have evolved in the time since the surveys were run. Preston New Road is the only shale gas hydraulic
669 fracturing activity in Europe that has been undertaken since our surveys were conducted in 2014; many
670 countries including Scotland had moratoria in place during this period, and, once the moratorium in
671 England was lifted in 2012, it took several years to obtain planning permissions to enable activities to
672 commence at the Preston New Road site, followed by repeated suspension of hydraulic fracturing
673 activities. We cannot postulate whether the rationale for the answers provided by participants might have
674 changed in light of these developments in the UK or internationally, including other incidences of felt
675 seismicity induced by hydraulic fracturing around the world (Verdon & Bommer 2020), and subsequent
676 advances in our understanding of induced seismicity and remaining knowledge gaps (Schultz et al, 2020).
677 Nonetheless, our study presents, for the first time, how language ambiguity around seismicity complicates
678 understanding of perceived risks, and sheds light on the apparent differences in views on the matter in
679 2014. Further, advances in knowledge and understanding on topics of public interest is common, but
680 presents additional communication challenges, in particular around the communication of uncertainty
681 (NMAS, 2018). Our findings suggest that language ambiguity around hydraulic fracturing induced
682 seismicity posed additional difficulties for understanding and communicating stakeholder risk perception,
683 and may have confounded risk communication.

684 Expertise is an ambiguous quality with multiple dimensions that can be difficult to assess (Lightbody and
685 Roberts, 2019). Many of our survey respondents were attending professional fora about shale gas, and
686 therefore might be considered to have expertise on the topic. Those who attended public lectures on
687 hydraulic fracturing could be said to be informed (and engaged) publics. Accordingly, we find that our
688 survey participants are, on the whole, much more decided about shale gas induced seismicity than the UK
689 general public (based on the University of Nottingham surveys as reported in O'Hara et al., 2016). Of the
690 relatively few participants in our survey who answered '*don't know*', their response did not necessarily
691 reflect lack of knowledge; several explained that the evidence was inconclusive or questioned the
692 definition of earthquake. Survey respondents who attended public events and who answered '*don't know*'
693 were more likely to express that they lack knowledge on the topic, and so we could conjecture that this is
694 the likely rationale when UK publics' answer '*don't know*'. A fourth closed answer category '*undecided*' or
695 '*it depends*' would capture these differences.

696 On one hand, fewer '*don't know*' responses might be expected of those working in shale gas topics or
697 attending public lectures on shale gas, given that they are knowledgeable about the topic, and reports at
698 the time conclude that risk of earthquakes from hydraulic fracturing is low, see Section 2.1. On the other
699 hand, fewer '*don't know*' responses might be somewhat surprising given that experts are expected to
700 have strong grasp of uncertainty within their field (e.g. Landström et al., 2015), and a range of
701 dependencies are provided in the qualitative responses. Further, it is now understood that the occurrence
702 of felt seismicity from hydraulic fracturing is highly site-specific (Butcher et al., 2017; Schultz et al., 2020;
703 Verdon and Bommer, 2020), and that "methods for predicting event maximum and magnitude...cannot
704 be viewed as reliable" (OGA, 2019 p3). Perhaps the certainty in expert views on shale gas and earthquakes
705 reflects also their motivations, such as support for the resource. While we cannot test this using our data,
706 we do note that over 90% of the most knowledgeable participants in our study supported shale gas
707 exploration compared to ~50% of the UK public in 2014 (O'Hara et al., 2016).

708 The proportions of those who '*do*' associate earthquakes with shale gas vary according to different factors
709 including the fora being attended (professional or public), the sources of information used to obtain
710 information about shale gas (outside of the event they were attending, expert reports vs academic papers
711 vs media) and job sector (academic, industry, civil service); in every case the closed survey results are

712 bimodal. While this might be interpreted to show polarisation of views both amongst experts and publics,
713 by examining the underlying rationale for the answers provided by our participants, we find this not to be
714 the case. Language ambiguity leads to differences in understanding of what defines or constitutes an
715 earthquake, and what is meant by ‘associating’ earthquakes with shale gas. As a result, participants with
716 similar underlying views or rationale give different responses to the closed question.

717 Regardless of whether our respondents ‘do’ or ‘do not’ associate earthquakes with shale gas, qualitative
718 answers most commonly express uncertainty around what magnitude of seismic event is understood to
719 be an earthquake. In particular, those who ‘do not’ associate earthquakes and shale gas question the
720 definition of an earthquake. The term *earthquake* (the phrase used in the survey question) is clearly felt
721 to be ambiguous by our survey respondents. Similar language ambiguities are expressed by experts
722 interviewed by Lampkin (2018), in which one said “*I would call them tremors not earthquakes, they are*
723 *very very small*” and another asserts that “*people who talk of earthquakes are sort of over-egging [over*
724 *doing] it a bit*”.

725 So, what constitutes an earthquake? Is it wrong or, indeed ‘over-egging it’ to describe a $M_L < 2$ event as
726 an earthquake? Technically, not (Kendall et al., 2019). In which case, how should earthquakes be
727 described? There are multiple scales with which to describe the size or properties of earthquakes,
728 including different scales of magnitude and energy release. However, there is no common descriptive
729 scale to define whether an event is a tremor, a micro-earthquake, small or large, or felt. Tremor has been
730 used to refer to low-frequency earthquake signals (Shelly et al., 2007), and terms such as micro- or nano-
731 seismicity often refer to the frequencies of the seismic energy. The degree to which an earthquake is felt
732 is captured by the European Macroseismic Scale, which includes classifications such as *not felt*, *scarcely*
733 *felt*, *weak*, and *largely observed*. Bohnhoff (2009) summarises terminology based on magnitude, including
734 *micro*, *small*, *moderate*, and *large*. The Oil and Gas Authority’s traffic light system infographic (Figure 1,
735 made by the Oil and Gas Authority) describes seismicity as *not felt*, *usually not felt*, *minor*, *light*, *moderate*,
736 *strong*, *major*, and *great*. Eaton et al. (2016) recognise the need for a terminology framework for induced
737 seismicity in particular to unify regulations in different jurisdictions, and propose that “earthquakes” and
738 “seismic events” should be distinguished by being felt or not, and therefore should refer to events $> M_L 2$
739 and $M_L < 2$, respectively. The Oil and Gas Authority’s traffic light system infographic (Figure 1, made by
740 the Oil and Gas Authority) describes seismicity as *not felt*, *usually not felt*, *minor*, *light*, *moderate*, *strong*,
741 *major*, and *great*.

742 In our study, we have not encountered any consistent use of such language when describing and reporting
743 hydraulic fracturing seismicity, i.e. there is no common descriptive scale, and certainly none that
744 translates into common language and understanding, even among experts. We find that while expert
745 reports commonly refer to ‘earthquakes’, ‘seismicity’ and ‘events’, many use additional qualifiers to
746 communicate the scale of the event by using terms such as ‘small’ or ‘tiny’, distinguishing between ‘felt’
747 or ‘perceived’ events, or by referring to the consequences of the seismicity using terms such ‘tremors’ or
748 ‘vibrations’ (Table 7). Importantly, none of the reports that we reviewed lay out what is meant by these
749 different phrases, though some specifically refer to felt seismicity, and stipulate that felt seismicity is
750 generally considered to be above $M_L 2$. We recommend that public-facing reports define technical or
751 descriptive terminology.

752 Similarly, our survey respondents include indicators of size, risk, and impacts in their qualitative answers.
753 They might select that they ‘do’ associate shale gas with earthquakes, but explain that ‘any induced
754 seismicity would be small or rare’, or they may select that they ‘do not’ associate shale gas with
755 earthquakes, because ‘any induced seismicity would be small or rare’ (see Table 7). Thus whether or not
756 a respondent associates shale gas with earthquakes does not reflect the perceived risk of seismicity. We
757 posit that had a definition of what was meant by the term earthquake been presented in the survey (e.g.
758 the release of seismic energy, or seismic events with magnitude greater than $2 M_L$), the answers to the
759 closed question would have been in much greater agreement.

760 These findings raise crucial questions around what constitutes an earthquake and to whom, and how
761 language is used to describe and communicate geological phenomena. A second important aspect that
762 our work highlights is the need to apply caution when using ambiguous terminology such as ‘earthquake’

763 in reports or surveys without defining the meaning of the phrase. But here, there are interesting tensions
764 or trade-offs. Terms such as ‘earthquake’ or ‘tremors’ might be used to avoid jargon, as they are
765 considered widely understood. However, as we show, what exactly constitutes an earthquake or tremor
766 is not well defined and so the use of these terms could lead to equivocal results. And these ambiguities
767 might vary geographically, too; the UK is a country of low natural background seismicity, and so while a
768 M₂ event might be considered an earthquake by the UK public, in regions with higher background activity,
769 other terms might be preferred.

770 But if our study finds that *associating* shale gas with earthquakes does not necessarily indicate concern
771 about the *risk* of earthquakes, what might this mean for understanding publics’ views on induced
772 seismicity? Do closed surveys with few questions or options capture the level of concern about induced
773 seismicity? Or might the use of the term ‘earthquake’ cause uncertainty in the responses? Might
774 participants be answering the same question differently depending on what they interpret ‘earthquake’
775 to mean? These issues highlight the limitations of closed questions in surveys; such questions are, by their
776 nature, constrained, which can bring limitations – including susceptibility to framing effects (Schuman &
777 Scott, 1987; Gaskell et al., 2017) which are recognised by Howell (2018). This is not to undermine closed-
778 survey research nor the results of studies we examined; there are strengths and weaknesses to all
779 research methods, including open survey questions (Schuman & Scott, 1987), which researchers will
780 carefully consider during the research design, execution and analysis. But altogether this raises important
781 questions around the methods used to capture, understand, and communicate stakeholder perspectives.
782 Might it be that, for comprehensive understanding of complex topics we must look to multi or mixed
783 method approaches (e.g. Walker & Baxter, 2019)?

784 Unlike the UK’s Traffic Light System, public risk tolerances of induced seismicity will not simply relate to
785 event magnitude; as we have outlined there are other important complicating and competing factors at
786 play (Evensen, 2018; Trutnevyte & Ejderyan, 2018; Szolucha, 2019). Understanding risk perception and
787 tolerances, influencing factors and values is important for public participation in socio-scientific decisions
788 (Dietz, 2013; Stern & Fineberg, 1996). As such, our findings about language ambiguity around induced
789 seismicity have implications for science communication and understanding of stakeholder preferences
790 and perceptions of risk. These implications are relevant across a range of different geological and energy
791 engineering technologies, many of which play a critical role in delivering a sustainable future (Stephenson
792 et al., 2019). We propose that a shared language to describe earthquakes should be developed and
793 adopted to enhance communication around induced seismicity amongst all stakeholders. Such approach
794 is common in risk communication and management practice (Fischhoff, 2013), and has recently been
795 called for by a community of UK shale gas researchers and practitioners (Brown et al., 2020). It supports
796 communication, and, as put by Trutnevyte & Ejderyan (2018), without such framework experts must
797 develop their communication approaches based on intuition and learning by doing [authors’ note: these
798 experiences are often described by practitioners as being ‘at the coal face’ or ‘on the front line’, indicating
799 the challenging pressured environment for learning]. As noted previously, language frameworks for
800 seismicity exist (such as the European Macroseismic Scale; Johnston, 1990; Bohnhoff, 2009, and so on)
801 but we find these are not in common use. While a language framework might facilitate risk
802 communication, it would not resolve communication and risk tolerance challenges around induced
803 seismicity. Any risk communication strategy must be individual to project, place and context, as well as
804 sensitive to issues of environmental and social equity and justice and heritage in which geogeneity is
805 involved (Trutnevyte & Ejderyan, 2018). The perceived risk may be greater for some technologies over
806 others (Knoblauch et al., 2017), and may evolve with time. However, the framework should establish a
807 common understanding through language, which is critical for dialogue on topics of public and political
808 interest. It is increasingly understood that sustainable development requires shared decision-making
809 pathways, for which communication approaches to support stakeholders to speak – and hear - the same
810 language are valuable.

811

812 **5. Conclusions**

813 This work has explored expert and non-expert perspectives on the risk of induced seismicity from shale
814 gas exploration in the UK. We find that range of terminologies have been inconsistently used to describe
815 seismic events to communicate risk of induced seismicity from hydraulic fracturing for shale gas. Such
816 language ambiguity has muddled our ability to understand the perceived risk of induced seismicity and
817 hydraulic fracturing amongst stakeholders, raising questions around what constitutes an earthquake and
818 to whom? Our insights present important implications for research, communication, and decision-making
819 on any uncertain, complex or sensitive topic. The immediate and long-lasting repercussions of using
820 “fracking bad language” is likely amplified by the political and environmental sensitivities around the shale
821 gas sector, as well as lack of familiarity of seismicity (natural and induced) to UK stakeholders. At its
822 simplest, this research presents a reminder of the importance of clearly defining technical and descriptive
823 terms, whether in expert reports, policy documents, or surveys. We suggest that a shared language to
824 describe earthquakes should be developed and adopted to improve understanding of perceived risks, and
825 to facilitate risk communication within and between expert and non-expert stakeholders. Our findings are
826 relevant to numerous geoscience applications, since many subsurface technologies deemed critical to a
827 low carbon future present risk of induced seismicity.

828 **6. Data Availability**

829 Full survey data are available at <https://doi.org/10.15129/a7a906c5-a77e-4a1c-b495-a2d441458d1d>

830 **7. Funding statement**

831 We thank ClimateXChange and the University of Strathclyde who funded Roberts’ position while this
832 research was undertaken.

833 **8. Ethics statement**

834 This research complied with the Ethics Policy and Procedure of the University of Strathclyde. Ethics
835 approval was granted for the survey research.

836 **9. Competing interests**

837 We declare no competing interests.

838 **10. Author contributions**

839 JR led the research design, data collection, analysis, and writing of this research, with CB in particular and
840 ZS contributing to all aspects.

841 **11. Acknowledgements**

842 We thank all conference and event organisers for supporting our work, as well as survey participants. We
843 also thank Dr Stella Pytharouli, Dr James Verdon, and Dr Stephen Hicks for their insights into earthquake
844 magnitudes and seismological terminology, and Dr Juan Alcalde for comments about language nuance
845 and translation. We would also like to thank Prof Brigitte Nerlich for early discussion about the relevance
846 of this work.
